

Lectures on Arithmetic Noncommutative Geometry

Matilde Marcolli

And indeed there will be time
To wonder “Do I dare?” and, “Do I dare?”
Time to turn back and descend the stair.

...

Do I dare
Disturb the Universe?

...

For I have known them all already, known them all;
Have known the evenings, mornings, afternoons,
I have measured out my life with coffee spoons.

...

I should have been a pair of ragged claws
Scuttling across the floors of silent seas.

...

No! I am not Prince Hamlet, nor was meant to be;
Am an attendant lord, one that will do
To swell a progress, start a scene or two

...

At times, indeed, almost ridiculous—
Almost, at times, the Fool.

...

We have lingered in the chambers of the sea
By sea-girls wreathed with seaweed red and brown
Till human voices wake us, and we drown.

(T.S. Eliot, “*The Love Song of J. Alfred Prufrock*”)

CHAPTER 1

Ouverture

Noncommutative geometry, as developed by Connes starting in the early '80s ([15], [17], [20]), extends the tools of ordinary geometry to treat spaces that are quotients, for which the usual “ring of functions”, defined as functions invariant with respect to the equivalence relation, is too small to capture the information on the “inner structure” of points in the quotient space. Typically, for such spaces functions on the quotients are just constants, while a nontrivial ring of functions, which remembers the structure of the equivalence relation, can be defined using a noncommutative algebra of coordinates, analogous to the non-commuting variables of quantum mechanics. These “quantum spaces” are defined by extending the Gelfand–Naimark correspondence

$$X \text{ loc.comp. Hausdorff space} \Leftrightarrow C_0(X) \text{ abelian } C^*\text{-algebra}$$

by dropping the commutativity hypothesis in the right hand side. The correspondence then becomes a definition of what is on the left hand side: a noncommutative space.

Such quotients are abundant in nature. They arise, for instance, from foliations. Several recent results also show that noncommutative spaces arise naturally in number theory and arithmetic geometry. The first instance of such connections between noncommutative geometry and number theory emerged in the work of Bost and Connes [8], which exhibits a very interesting noncommutative space with remarkable arithmetic properties related to class field theory. This reveals a very useful dictionary that relates the phenomena of spontaneous symmetry breaking in quantum statistical mechanics to the mathematics of Galois theory. This space can be viewed as the space of 1-dimensional \mathbb{Q} -lattices up to scale, modulo the equivalence relation of commensurability (*cf.* [29]). This space is closely related to the noncommutative space used by Connes to obtain a spectral realization of the zeros of the Riemann zeta function, [22]. In fact, this is again the space of commensurability classes of 1-dimensional \mathbb{Q} -lattices, but with the scale factor also taken into account.

More recently, other results that point to deep connections between noncommutative geometry and number theory appeared in the work

of Connes and Moscovici [33] [34] on the modular Hecke algebras. This shows that the Rankin–Cohen brackets, an important algebraic structure on modular forms [94], have a natural interpretation in the language of noncommutative geometry, in terms of the Hopf algebra of the transverse geometry of codimension one foliations. The modular Hecke algebras, which naturally combine products and action of Hecke operators on modular forms, can be viewed as the “holomorphic part” of the algebra of coordinates on the space of commensurability classes of 2-dimensional \mathbb{Q} -lattices constructed in joint work of Connes and the author [29].

Cases of occurrences of interesting number theory within noncommutative geometry can be found in the classification of noncommutative three spheres by Connes and Dubois–Violette [26] [27]. Here the corresponding moduli space has a ramified cover by a noncommutative nilmanifold, where the noncommutative analog of the Jacobian of this covering map is expressed naturally in terms of the ninth power of the Dedekind eta function. Another such case occurs in Connes’ calculation [24] of the explicit cyclic cohomology Chern character of a spectral triple on $SU_q(2)$ defined by Chakraborty and Pal [12].

Other instances of noncommutative spaces that arise in the context of number theory and arithmetic geometry can be found in the noncommutative compactification of modular curves of [25], [70]. This noncommutative space is again related to the noncommutative geometry of \mathbb{Q} -lattices. In fact, it can be seen as a stratum in the compactification of the space of commensurability classes of 2-dimensional \mathbb{Q} -lattices (*cf.* [29]).

Another context in which noncommutative geometry provides a useful tool for arithmetic geometry is in the description of the totally degenerate fibers at “arithmetic infinity” of arithmetic varieties over number fields, analyzed in joint work of the author with Katia Consani ([36], [37], [38], [39]).

The present text is based on a series of lectures given by the author at Vanderbilt University in May 2004, as well as on previous series of lectures given at the Fields Institute in Toronto (2002), at the University of Nottingham (2003), and at CIRM in Luminy (2004).

The main focus of the lectures is the noncommutative geometry of modular curves (following [70]) and of the archimedean fibers of arithmetic varieties (following [36]). A chapter on the noncommutative space of commensurability classes of 2-dimensional \mathbb{Q} -lattices is also included (following [29]). The text reflects very closely the style of the lectures. In particular, we have tried more to convey the general picture than the details of the proofs of the specific results. Though

many proofs have not been included in the text, the reader will find references to the relevant literature, where complete proofs are provided (in particular [29], [36], and [70]).

More explicitly, the text is organized as follows:

- We start by recalling a few preliminary notions of noncommutative geometry (following [20]).
- The second chapter describes how various arithmetic properties of modular curves can be seen by their “noncommutative boundary”. This part is based on the joint work of Yuri Manin and the author. The main references are [70], [71], [72].
- We review briefly the work of Connes and the author [29] on the noncommutative geometry of commensurability classes of \mathbb{Q} -lattices. The relation of the noncommutative space of commensurability classes of \mathbb{Q} -lattices to the Hilbert 12th problem of explicit class field theory is based on ongoing work of Connes, Ramachandran and the author [31], on the original work of Bost and Connes [8] and on Manin’s real multiplication program [62] [63].
- The noncommutative geometry of the fibers at “arithmetic infinity” of varieties over number fields is based on joint work of Consani and the author, for which the references are [36], [37], [38], [39], [40]. This chapter also contains a detailed account of Manin’s formula for the Green function of Arakelov geometry for arithmetic surfaces, based on [66], and a proposed physical interpretation of this formula, as in [69].

1. The NCG dictionary

There is a dictionary (*cf.* [20]) relating concepts of ordinary geometry to the corresponding counterparts in noncommutative geometry. The entries can be arranged according to the finer structures considered on the underlying space, roughly according to the following table.

measure theory	von Neumann algebras
topology	C^* -algebras
smooth structures	smooth subalgebras
Riemannian geometry	spectral triples

It is important to notice that, usually, the notions of noncommutative geometry are “richer” than the corresponding entries of the dictionary on the commutative side. For instance, as Connes discovered, noncommutative measure spaces (von Neumann algebras) come endowed with a natural time evolution which is trivial in the commutative case.

Similarly, at the level of topology one often sees phenomena that are closer to rigid analytic geometry. This is the case, for instance, with the noncommutative tori T_θ , which already at the C^* -algebra level exhibit moduli that behave much like moduli of one-dimensional complex tori (elliptic curves) in the commutative case.

In the context we are going to discuss this richer structure of noncommutative spaces is crucial, as it permits us to use tools like C^* -algebras (topology) to study the properties more rigid spaces like algebraic or arithmetic varieties.

2. Noncommutative spaces

The way to assign the algebra of coordinates to a quotient space $X = Y/\sim$ can be explained in a short slogan as follows:

- Functions on Y with $f(a) = f(b)$ for $a \sim b$. **Poor!**
- Functions f_{ab} on the graph of the equivalence relation. **Good!**

The second description leads to a noncommutative algebra, as the product, determined by the groupoid law of the equivalence relation, has the form of a convolution product (like the product of matrices).

For sufficiently *nice* quotients, even though the two notions are not the same, they are related by Morita equivalence, which is the suitable notion of “isomorphism” between noncommutative spaces. For more general quotients, however, the two notions truly differ and the second one is the only one that allows one to continue to make sense of geometry on the quotient space.

A very simple example illustrating the above situation is the following (*cf.* [23]). Consider the topological space $Y = [0, 1] \times \{0, 1\}$ with the equivalence relation $(x, 0) \sim (x, 1)$ for $x \in (0, 1)$. By the first method one only obtains constant functions \mathbb{C} , while by the second method one obtains

$$\{f \in C([0, 1]) \otimes M_2(\mathbb{C}) : f(0) \text{ and } f(1) \text{ diagonal} \}$$

which is an interesting nontrivial algebra.

The idea of preserving the information on the structure of the equivalence relation in the description of quotient spaces has analogs in Grothendieck’s theory of stacks in algebraic geometry.

2.1. Morita equivalence. In noncommutative geometry, isomorphisms of C^* -algebras are too restrictive to provide a good notion of isomorphisms of noncommutative spaces. The correct notion is provided by Morita equivalence of C^* -algebras.

We have equivalent C^* -algebras $\mathcal{A}_1 \sim \mathcal{A}_2$ if there exists a bimodule \mathcal{M} , which is a right Hilbert \mathcal{A}_1 module with an \mathcal{A}_1 -valued inner product

$\langle \cdot, \cdot \rangle_{\mathcal{A}_1}$, and a left Hilbert \mathcal{A}_2 -module with an \mathcal{A}_2 -valued inner product $\langle \cdot, \cdot \rangle_{\mathcal{A}_2}$, such that we have:

- We obtain all \mathcal{A}_i as the closure of the span of

$$\{\langle \xi_1, \xi_2 \rangle_{\mathcal{A}_i} : \xi_1, \xi_2 \in \mathcal{M}\}.$$

- $\forall \xi_1, \xi_2, \xi_3 \in \mathcal{M}$ we have

$$\langle \xi_1, \xi_2 \rangle_{\mathcal{A}_1} \xi_3 = \xi_1 \langle \xi_2, \xi_3 \rangle_{\mathcal{A}_2}.$$

- \mathcal{A}_1 and \mathcal{A}_2 act on \mathcal{M} by bounded operators,

$$\langle a_2 \xi, a_2 \xi \rangle_{\mathcal{A}_1} \leq \|a_2\|^2 \langle \xi, \xi \rangle_{\mathcal{A}_1} \quad \langle a_1 \xi, a_1 \xi \rangle_{\mathcal{A}_2} \leq \|a_1\|^2 \langle \xi, \xi \rangle_{\mathcal{A}_2}$$

for all $a_1 \in \mathcal{A}_1$, $a_2 \in \mathcal{A}_2$, $\xi \in \mathcal{M}$.

This notion of equivalence roughly means that one can transfer modules back and forth between the two algebras.

2.2. The tools of noncommutative geometry. Once one identifies in a specific problem a space that, by its nature of quotient of the type described above, is best described as a noncommutative space, there is a large set of well developed techniques that one can use to compute invariants and extract essential information from the geometry. The following is a list of some such techniques, some of which will make their appearance in the cases treated in these notes.

- Topological invariants: K-theory
- Hochschild and cyclic cohomology
- Homotopy quotients, assembly map (Baum-Connes)
- Metric structure: Dirac operator, spectral triples
- Characteristic classes, zeta functions

We will recall the necessary notions when needed. We now begin by taking a closer look at the analog in the noncommutative world of Riemannian geometry, which is provided by Connes' notion of spectral triples.

3. Spectral triples

Spectral triples are a crucial notion in noncommutative geometry. They provide a powerful and flexible generalization of the classical structure of a Riemannian manifold. The two notions agree on a commutative space. In the usual context of Riemannian geometry, the definition of the infinitesimal element ds on a smooth spin manifold can be expressed in terms of the inverse of the classical Dirac operator D . This is the key remark that motivates the theory of spectral triples. In particular, the geodesic distance between two points on the manifold is defined in terms of D^{-1} (*cf.* [20] §VI). The spectral triple

(A, H, D) that describes a classical Riemannian spin manifold is given by the algebra A of complex valued smooth functions on the manifold, the Hilbert space H of square integrable spinor sections, and the classical Dirac operator D . These data determine completely and uniquely the Riemannian geometry on the manifold. It turns out that, when expressed in this form, the notion of spectral triple extends to more general non-commutative spaces, where the data (A, H, D) consist of a C^* -algebra A (or more generally of some smooth subalgebra of a C^* -algebra) with a representation in the algebra of bounded operators on a separable Hilbert space H , and an operator D on H that verifies the main properties of a Dirac operator.

We recall the basic setting of Connes theory of spectral triples. For a more complete treatment see [20], [21], [32].

DEFINITION 3.1. *A spectral triple $(\mathcal{A}, \mathcal{H}, D)$ consists of a C^* -algebra \mathcal{A} with a representation*

$$\rho : \mathcal{A} \rightarrow \mathcal{B}(\mathcal{H})$$

in the algebra of bounded operators on a separable Hilbert space \mathcal{H} , and an operator D (called the Dirac operator) on \mathcal{H} , which satisfies the following properties:

- (1) *D is self-adjoint.*
- (2) *For all $\lambda \notin \mathbb{R}$, the resolvent $(D - \lambda)^{-1}$ is a compact operator on \mathcal{H} .*
- (3) *The commutator $[D, \rho(a)]$ is a bounded operator on \mathcal{H} , for all $a \in \mathcal{A}_0 \subset \mathcal{A}$, a dense involutive subalgebra of \mathcal{A} .*

The property 2. of Definition 3.1 can be regarded as a generalization of the ellipticity property of the standard Dirac operator on a compact manifold. In the case of ordinary manifolds, we can consider as subalgebra \mathcal{A}_0 the algebra of smooth functions, as a subalgebra of the commutative C^* -algebra of continuous functions. In fact, in the classical case of Riemannian manifolds, property 3. is equivalent the Lipschitz condition, hence it is satisfied by a larger class than that of smooth functions.

Thus, the basic geometric structure encoded by the theory of spectral triples is Riemannian geometry, but in more refined cases, such as Kähler geometry, the additional structure can be easily encoded as additional symmetries. We will see, for instance, a case (*cf.* [36] [40]) where the algebra involves the action of the Lefschetz operator of a compact Kähler manifold, hence it encodes the information (at the cohomological level) on the Kähler form.

Since we are mostly interested in the relations between noncommutative geometry and arithmetic geometry and number theory, an especially interesting feature of spectral triples is that they have an associated family of zeta functions and a theory of volumes and integration, which is related to special values of these zeta functions. (The following treatment is based on [20], [21].)

3.1. Volume form. A spectral triple $(\mathcal{A}, \mathcal{H}, D)$ is said to be of dimension n , or *n-summable* if the operator $|D|^{-n}$ is an infinitesimal of order one, which means that the eigenvalues $\lambda_k(|D|^{-n})$ satisfy the estimate $\lambda_k(|D|^{-n}) = O(k^{-1})$.

For a positive compact operator T such that

$$\sum_{j=0}^{k-1} \lambda_j(T) = O(\log k),$$

the Dixmier trace $\text{Tr}_\omega(T)$ is the coefficient of this logarithmic divergence, namely

$$(1.1) \quad \text{Tr}_\omega(T) = \lim_\omega \frac{1}{\log k} \sum_{j=1}^k \lambda_j(T).$$

Here the notation \lim_ω takes into account the fact that the sequence

$$S(k, T) := \frac{1}{\log k} \sum_{j=1}^k \lambda_j(T)$$

is bounded though possibly non-convergent. For this reason, the usual notion of limit is replaced by a choice of a linear form \lim_ω on the set of bounded sequences satisfying suitable conditions that extend analogous properties of the limit. When the sequence $S(k, T)$ converges (1.1) is just the ordinary limit $\text{Tr}_\omega(T) = \lim_{k \rightarrow \infty} S(k, T)$. So defined, the Dixmier trace (1.1) extends to any compact operator that is an infinitesimal of order one, since any such operator is the difference of two positive ones. The operators for which the Dixmier trace does not depend on the choice of the linear form \lim_ω are called *measurable operators*.

On a non-commutative space the operator $|D|^{-n}$ generalizes the notion of a volume form. The volume is defined as

$$(1.2) \quad V = \text{Tr}_\omega(|D|^{-n}).$$

More generally, consider the algebra $\tilde{\mathcal{A}}$ generated by \mathcal{A} and $[D, \mathcal{A}]$. Then, for $a \in \tilde{\mathcal{A}}$, integration with respect to the volume form $|D|^{-n}$ is

defined as

$$(1.3) \quad \int a := \frac{1}{V} \text{Tr}_\omega(a|D|^{-n}).$$

The usual notion of integration on a Riemannian spin manifold M can be recovered in this context (*cf.* [20], [58]) through the formula (n even):

$$\int_M f dv = (2^{n-[n/2]-1} \pi^{n/2} n \Gamma(n/2)) \text{Tr}_\omega(f|D|^{-n}).$$

Here D is the classical Dirac operator on M associated to the metric that determines the volume form dv , and f in the right hand side is regarded as the multiplication operator acting on the Hilbert space of square integrable spinors on M .

3.2. Zeta functions. An important function associated to the Dirac operator D of a spectral triple $(\mathcal{A}, \mathcal{H}, D)$ is its zeta function

$$(1.4) \quad \zeta_D(z) := \text{Tr}(|D|^{-z}) = \sum_\lambda \text{Tr}(\Pi(\lambda, |D|)) \lambda^{-z},$$

where $\Pi(\lambda, |D|)$ denotes the orthogonal projection on the eigenspace $E(\lambda, |D|)$.

An important result in the theory of spectral triples ([20] §IV Proposition 4) relates the volume (1.2) with the residue of the zeta function (1.4) at $s = 1$ through the formula

$$(1.5) \quad V = \lim_{s \rightarrow 1^+} (s-1) \zeta_D(s) = \text{Res}_{s=1} \text{Tr}(|D|^{-s}).$$

There is a family of zeta functions associated to a spectral triple $(\mathcal{A}, \mathcal{H}, D)$, to which (1.4) belongs. For an operator $a \in \hat{\mathcal{A}}$, we can define the zeta functions

$$(1.6) \quad \zeta_{a,D}(z) := \text{Tr}(a|D|^{-z}) = \sum_\lambda \text{Tr}(a \Pi(\lambda, |D|)) \lambda^{-z}$$

and

$$(1.7) \quad \zeta_{a,D}(s, z) := \sum_\lambda \text{Tr}(a \Pi(\lambda, |D|)) (s - \lambda)^{-z}.$$

These zeta functions are related to the heat kernel $e^{-t|D|}$ by Mellin transform

$$(1.8) \quad \zeta_{a,D}(z) = \frac{1}{\Gamma(z)} \int_0^\infty t^{z-1} \text{Tr}(a e^{-t|D|}) dt$$

where

$$(1.9) \quad \text{Tr}(a e^{-t|D|}) = \sum_\lambda \text{Tr}(a \Pi(\lambda, |D|)) e^{-t\lambda} =: \theta_{a,D}(t).$$

Similarly,

$$(1.10) \quad \zeta_{a,D}(s, z) = \frac{1}{\Gamma(z)} \int_0^\infty \theta_{a,D,s}(t) t^{z-1} dt$$

with

$$(1.11) \quad \theta_{a,D,s}(t) := \sum_\lambda \text{Tr}(a \Pi(\lambda, |D|)) e^{(s-\lambda)t}.$$

Under suitable hypothesis on the asymptotic expansion of (1.11) (*cf.* Theorem 2.7-2.8 of [65] §2), the functions (1.6) and (1.7) admit a unique analytic continuation (*cf.* [32]) and there is an associated regularized determinant in the sense of Ray–Singer (*cf.* [84]):

$$(1.12) \quad \det_{\infty, a, D}(s) := \exp \left(-\frac{d}{dz} \zeta_{a,D}(s, z) \Big|_{z=0} \right).$$

The family of zeta functions (1.6) also provides a refined notion of dimension for a spectral triple $(\mathcal{A}, \mathcal{H}, D)$, called the *dimension spectrum*. This is a subset $\Sigma = \Sigma(\mathcal{A}, \mathcal{H}, D)$ in \mathbb{C} with the property that all the zeta functions (1.6), as a varies in $\tilde{\mathcal{A}}$, extend holomorphically to $\mathbb{C} \setminus \Sigma$.

Examples of spectral triples with dimension spectrum not contained in the real line can be constructed out of Cantor sets.

3.3. Index map. The data of a spectral triple determine an index map. In fact, the self adjoint operator D has a polar decomposition, $D = F|D|$, where $|D| = \sqrt{D^2}$ is a positive operator and F is a sign operator, *i.e.* $F^2 = I$. Following [20] and [21] one defines a cyclic cocycle

$$(1.13) \quad \tau(a^0, a^1, \dots, a^n) = \text{Tr}(a^0 [F, a^1] \cdots [F, a^n]),$$

where n is the dimension of the spectral triple. For n even Tr should be replaced by a super trace, as usual in index theory. This cocycle pairs with the K -groups of the algebra \mathcal{A} (with K_0 in the even case and with K_1 in the odd case), and defines a class τ in the cyclic cohomology $HC^n(\mathcal{A})$ of \mathcal{A} . The class τ is called the Chern character of the spectral triple $(\mathcal{A}, \mathcal{H}, D)$.

In the case when the spectral triple $(\mathcal{A}, \mathcal{H}, D)$ has *discrete* dimension spectrum Σ , there is a local formula for the cyclic cohomology Chern character (1.13), analogous to the local formula for the index in the commutative case. This is obtained by producing Hochschild representatives (*cf.* [21], [32])

$$(1.14) \quad \varphi(a^0, a^1, \dots, a^n) = \text{Tr}_\omega(a^0 [D, a^1] \cdots [D, a^n] |D|^{-n}).$$

3.4. Infinite dimensional geometries. The main difficulty in constructing specific examples of spectral triples is to produce an operator D that at the same time has bounded commutators with the elements of \mathcal{A} and produces a non-trivial index map.

It sometimes happens that a noncommutative space does not admit a finitely summable spectral triple, namely one such that the operator $|D|^{-p}$ is of trace class for some $p > 0$. Obstructions to the existence of such spectral triples are analyzed in [19]. It is then useful to consider a weaker notion, namely that of θ -summable spectral triples. These have the property that the Dirac operator satisfies

$$(1.15) \quad \mathrm{Tr}(e^{-tD^2}) < \infty \quad \forall t > 0.$$

Such spectral triples should be thought of as “infinite dimensional non-commutative geometries”.

We’ll see examples of spectral triples that are θ -summable but not finitely summable, because of the growth rate of the multiplicities of eigenvalues.

3.5. Spectral triples and Morita equivalences. If $(\mathcal{A}_1, \mathcal{H}, D)$ is a spectral triple, and we have a Morita equivalence $\mathcal{A}_1 \sim \mathcal{A}_2$ implemented by a bimodule \mathcal{M} which is a finite projective right Hilbert module over \mathcal{A}_1 , then we can transfer the spectral triple from \mathcal{A}_1 to \mathcal{A}_2 .

First consider the \mathcal{A}_1 -bimodule Ω_D^1 generated by

$$\{a_1[D, b_1] : a_1, b_1 \in \mathcal{A}_1\}.$$

We define a connection

$$\nabla : \mathcal{M} \rightarrow \mathcal{M} \otimes_{\mathcal{A}_1} \Omega_D^1$$

by requiring that

$$\nabla(\xi a_1) = (\nabla\xi)a_1 + \xi \otimes [D, a_1],$$

$\forall \xi \in \mathcal{M}, \forall a_1 \in \mathcal{A}_1$ and $\forall \xi_1, \xi_2 \in \mathcal{M}$. We also require that

$$\langle \xi_1, \nabla \xi_2 \rangle_{\mathcal{A}_1} - \langle \nabla \xi_1, \xi_2 \rangle_{\mathcal{A}_1} = [D, \langle \xi_1, \xi_2 \rangle_{\mathcal{A}_1}].$$

This induces a spectral triple $(\mathcal{A}_2, \tilde{\mathcal{H}}, \tilde{D})$ obtained as follows.

The Hilbert space is given by $\tilde{\mathcal{H}} = \mathcal{M} \otimes_{\mathcal{A}_1} \mathcal{H}$. The action takes the form

$$a_2(\xi \otimes_{\mathcal{A}_1} x) := (a_2\xi) \otimes_{\mathcal{A}_1} x.$$

The Dirac operator is given by

$$\tilde{D}(\xi \otimes x) = \xi \otimes D(x) + (\nabla\xi)x.$$

Notice that we need a Hermitian connection ∇ , because commutators $[D, a]$ for $a \in \mathcal{A}_1$ are non-trivial, hence $1 \otimes D$ would not be well defined on $\tilde{\mathcal{H}}$.

3.6. K-theory of C^* -algebras. The K -groups are important invariants of C^* -algebras that capture information on the topology of non-commutative spaces, much like cohomology (or more appropriately topological K -theory) captures information on the topology of ordinary spaces. For a C^* -algebra \mathcal{A} , we have:

3.6.1. $K_0(\mathcal{A})$. This group is obtained by considering idempotents ($p^2 = p$) in matrix algebras over \mathcal{A} . Notice that, for a C^* -algebra, it is sufficient to consider projections ($P^2 = P, P = P^*$). In fact, we can always replace an idempotent p by a projection $P = pp^*(1 - (p - p^*)^2)^{-1}$, preserving the von Neumann equivalence. Then we consider $P \simeq Q$ if and only if $P = X^*X Q = XX^*$, for $X =$ partial isometry ($X = XX^*X$), and we impose the stable equivalence: $P \sim Q$, for $P \in \mathcal{M}_n(\mathcal{A})$ and $Q \in \mathcal{M}_m(\mathcal{A})$, if and only if there exists R a projection with $P \oplus R \simeq Q \oplus R$. We define $K_0(\mathcal{A})^+$ to be the monoid of projections modulo these equivalences and we let $K_0(\mathcal{A})$ be its Grothendieck group.

3.6.2. $K_1(\mathcal{A})$. Consider the group $\mathrm{GL}_n(\mathcal{A})$ of invertible elements in the matrix algebra $\mathcal{M}_n(\mathcal{A})$, and $\mathrm{GL}_n^0(\mathcal{A})$ the identity component of $\mathrm{GL}_n(\mathcal{A})$. The morphism

$$\mathrm{GL}_n(\mathcal{A}) \rightarrow \mathrm{GL}_{n+1}(\mathcal{A}) \quad a \mapsto \begin{pmatrix} a & 0 \\ 0 & 1 \end{pmatrix}$$

induces

$$\mathrm{GL}_n(\mathcal{A})/\mathrm{GL}_n^0(\mathcal{A}) \rightarrow \mathrm{GL}_{n+1}(\mathcal{A})/\mathrm{GL}_{n+1}^0(\mathcal{A}).$$

The group $K_1(\mathcal{A})$ is defined as the direct limit of these morphisms. Notice that $K_1(\mathcal{A})$ is abelian even if the $\mathrm{GL}_n(\mathcal{A})/\mathrm{GL}_n^0(\mathcal{A})$ are not.

In general, K -theory is not easy to compute. This led to two fundamental developments in noncommutative geometry. The first is cyclic cohomology (*cf.* [17], [18], [20]), introduced by Connes in 1981, which provides cycles that pair with K -theory, and a Chern character. The second development is the geometrically defined K -theory of Baum–Connes [6] and the assembly map

$$(1.16) \quad \mu : K^*(X, G) \rightarrow K_*(C_0(X) \rtimes G)$$

from the geometric to the analytic K -theory. Much work went, in recent years, into exploring the range of validity of the Baum–Connes conjecture, according to which the assembly map gives an isomorphism between these two different notions of K -theory.

CHAPTER 2

Noncommutative modular curves

The results of this section are mostly based on the joint work of Yuri Manin and the author [70], with additional material from [71] and [72]. We include necessary preliminary notions on modular curves and on noncommutative tori, respectively based on the papers [68] and [15], [85].

We first recall some aspects of the classical theory of modular curves. We will then show that these notions can be entirely recovered and enriched through the analysis of a noncommutative space associated to a compactification of modular curves, which includes noncommutative tori as possible degenerations of elliptic curves.

1. Modular curves

Let G be a finite index subgroup of the modular group $\Gamma = \mathrm{PSL}(2, \mathbb{Z})$, and let X_G denote the quotient

$$(2.1) \quad X_G := G \backslash \mathbb{H}^2$$

where \mathbb{H}^2 is the 2-dimensional real hyperbolic plane, namely the upper half plane $\{z \in \mathbb{C} : \Im z > 0\}$ with the metric $ds^2 = |dz|^2 / (\Im z)^2$. Equivalently, we identify \mathbb{H}^2 with the Poincaré disk $\{z : |z| < 1\}$ with the metric $ds^2 = 4|dz|^2 / (1 - |z|^2)^2$.

We denote the quotient map by $\phi : \mathbb{H}^2 \rightarrow X_G$.

Let \mathbb{P} denote the coset space $\mathbb{P} := \Gamma/G$. We can write the quotient X_G equivalently as

$$X_G = \Gamma \backslash (\mathbb{H}^2 \times \mathbb{P}).$$

A tessellation of the hyperbolic plane \mathbb{H}^2 by fundamental domains for the action of $\mathrm{PSL}(2, \mathbb{Z})$ is illustrated in Figure 1. The action of $\mathrm{PSL}(2, \mathbb{Z})$ by fractional linear transformations $z \mapsto \frac{az+b}{cz+d}$ is usually written in terms of the generators $S : z \mapsto -1/z$ and $T : z \mapsto z + 1$ (inversion and translation). Equivalently, $\mathrm{PSL}(2, \mathbb{Z})$ can be identified with the free product $\mathrm{PSL}(2, \mathbb{Z}) \cong \mathbb{Z}/2 * \mathbb{Z}/3$, with generators σ, τ of order two and three, respectively given by $\sigma = S$ and $\tau = ST$.

FIGURE 1. Fundamental domains for $\mathrm{PSL}(2, \mathbb{Z})$

An example of finite index subgroups is given by the congruence subgroups $\Gamma_0(N) \subset \Gamma$, of matrices

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

with $c \equiv 0 \pmod{N}$. A fundamental domain for $\Gamma_0(N)$ is given by $F \cup_{k=0}^{N-1} ST^k(F)$, where F is a fundamental domain for Γ as in Figure 1¹.

The quotient space X_G has the structure of a non-compact Riemann surface. This has a natural algebro-geometric compactification, which consists of adding the cusp points (points at infinity). The cusp points are identified with the quotient

$$(2.2) \quad G \backslash \mathbb{P}^1(\mathbb{Q}) \simeq \Gamma \backslash (\mathbb{P}^1(\mathbb{Q}) \times \mathbb{P}).$$

Thus, we write the compactification as

$$(2.3) \quad \overline{X_G} := G \backslash (\mathbb{H}^2 \cup \mathbb{P}^1(\mathbb{Q})) \simeq \Gamma \backslash ((\mathbb{H}^2 \cup \mathbb{P}^1(\mathbb{Q})) \times \mathbb{P}).$$

The modular curve X_Γ , for $\Gamma = \mathrm{SL}(2, \mathbb{Z})$ is the moduli space of elliptic curves, with the point $\tau \in \mathbb{H}^2$ parameterizing the lattice $\Lambda = \mathbb{Z} \oplus \tau\mathbb{Z}$ in \mathbb{C} and the corresponding elliptic curve uniformized by

$$E_\tau = \mathbb{C}/\Lambda.$$

¹Figures 1 and 2 are taken from Curt McMullen's Gallery

The unique cusp point corresponds to the degeneration of the elliptic curve to the cylinder \mathbb{C}^* , when $\tau \rightarrow \infty$ in the upper half plane.

The other modular curves, obtained as quotients X_G by a congruence subgroup, can also be interpreted as moduli spaces: they are moduli spaces of elliptic curves with level structure. Namely, for elliptic curves $E = \mathbb{C}/\Lambda$, this is an additional information on the torsion points $\frac{1}{N}\Lambda/\Lambda \subset \mathbb{Q}\Lambda/\Lambda$ of some level N .

For instance, in the case of the principal congruence subgroups $\Gamma(N)$ of matrices

$$M = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma$$

such that $M \equiv Id \pmod{N}$, points in the modular curve $\Gamma(N) \backslash \mathbb{H}^2$ classify elliptic curves $E_{tau} = \mathbb{C}/\Lambda$, with $\Lambda = \mathbb{Z} + \mathbb{Z}\tau$, together with a basis $\{1/N, \tau/N\}$ for the torsion subgroup $\frac{1}{N}\Lambda/\Lambda$. The projection $X_{\Gamma(N)} \rightarrow X_{\Gamma}$ forgets the extra structure.

In the case of the groups $\Gamma_0(N)$, points in the quotient $\Gamma_0(N) \backslash \mathbb{H}^2$ classify elliptic curves together with a cyclic subgroup of E_{τ} of order N . This extra information is equivalent to an isogeny $\phi : E_{\tau} \rightarrow E_{\tau'}$ where the cyclic group is $\text{Ker}(\phi)$. Recall that an isogeny is a morphism $\phi : E_{\tau} \rightarrow E_{\tau'}$ such that $\phi(0) = 0$. These are implemented by the action of $\text{GL}_2^+(\mathbb{Q})$ on \mathbb{H}^2 , namely E_{τ} and $E_{\tau'}$ are isogenous if and only if τ and τ' in \mathbb{H}^2 are in the same orbit of $\text{GL}_2^+(\mathbb{Q})$.

1.1. Modular symbols. Given two points $\alpha, \beta \in \mathbb{H}^2 \cup \mathbb{P}^1(\mathbb{Q})$, a real homology class $\{\alpha, \beta\}_G \in H_1(X_G, \mathbb{R})$ is defined as

$$\{\alpha, \beta\}_G : \omega \mapsto \int_{\alpha}^{\beta} \phi^*(\omega),$$

where ω are holomorphic differentials on X_G , and the integration of the pullback to \mathbb{H}^2 is along the geodesic arc connecting two cusps α and β (*cf.* Figure 2).

The modular symbols $\{\alpha, \beta\}_G$ satisfy the additivity and invariance properties

$$\{\alpha, \beta\}_G + \{\beta, \gamma\}_G = \{\alpha, \gamma\}_G,$$

and

$$\{g\alpha, g\beta\}_G = \{\alpha, \beta\}_G,$$

for all $g \in G$.

Because of additivity, it is sufficient to consider modular symbols of the form $\{0, \alpha\}$ with $\alpha \in \mathbb{Q}$,

$$\{0, \alpha\}_G = - \sum_{k=1}^n \{g_k(\alpha) \cdot 0, g_k(\alpha) \cdot i\infty\}_G,$$

FIGURE 2. Geodesics between cusps define modular symbols

where α has continued fraction expansion $\alpha = [a_0, \dots, a_n]$, and

$$g_k(\alpha) = \begin{pmatrix} p_{k-1}(\alpha) & p_k(\alpha) \\ q_{k-1}(\alpha) & q_k(\alpha) \end{pmatrix},$$

with p_k/q_k the successive approximations, and $p_n/q_n = \alpha$.

In the classical theory of the modular symbols of [68], [77] (cf. also [50], [76]) cohomology classes obtained from cusp forms are evaluated against relative homology classes given by modular symbols, namely, given a cusp form Φ on \mathbb{H} , obtained as pullback $\Phi = \varphi^*(\omega)/dz$ under the quotient map $\varphi : \mathbb{H} \rightarrow X_G$, we denote by $\Delta_\omega(s)$ the intersection numbers $\Delta_\omega(s) = \int_{g_s(0)}^{g_s(i\infty)} \Phi(z)dz$, with $g_s G = s \in \mathbb{P}$. These intersection numbers can be interpreted in terms of special values of L -functions associated to the automorphic form which determines the cohomology class.

We rephrase this in cohomological terms following [77]. We denote by \tilde{I} and \tilde{R} the elliptic points, namely the orbits $\tilde{I} = \Gamma \cdot i$ and $\tilde{R} = \Gamma \cdot \rho$. We denote by I and R the image in X_G of the elliptic points

$$I = G \backslash \tilde{I} \quad R = G \backslash \tilde{R},$$

with $\rho = e^{\pi i/3}$. We use the notation

$$(2.4) \quad H_A^B := H_1(\overline{X_G} \setminus A, B; \mathbb{Z}).$$

These groups are related by the pairing

$$(2.5) \quad H_A^B \times H_B^A \rightarrow \mathbb{Z}.$$

The modular symbols $\{g(0), g(i\infty)\}$, for $gG \in \mathbb{P}$, define classes in H^{cusps} . For σ and τ the generators of $\text{PSL}(2, \mathbb{Z})$ with $\sigma^2 = 1$ and $\tau^3 = 1$, we set

$$(2.6) \quad \mathbb{P}_I = \langle \sigma \rangle \backslash \mathbb{P} \quad \text{and} \quad \mathbb{P}_R = \langle \tau \rangle \backslash \mathbb{P}.$$

There is an isomorphism $\mathbb{Z}^{|\mathbb{P}|} \cong H_{\text{cusps} \cup I}^R$. Given the exact sequences

$$0 \rightarrow H_{\text{cusps}} \xrightarrow{\iota'} H_{\text{cusps}}^R \xrightarrow{\pi_R} \mathbb{Z}^{|\mathbb{P}_R|} \rightarrow \mathbb{Z} \rightarrow 0$$

and

$$0 \rightarrow \mathbb{Z}^{|\mathbb{P}_I|} \rightarrow H_{\text{cusps} \cup I}^R \xrightarrow{\pi_I} H_{\text{cusps}}^R \rightarrow 0,$$

the image $\pi_I(\tilde{x}) \in H_{\text{cusps}}^R$ of an element $\tilde{x} = \sum_{s \in \mathbb{P}} \lambda_s s$ in $\mathbb{Z}^{|\mathbb{P}|} \cong H_{\text{cusps} \cup I}^R$ represents an element $x \in H_{\text{cusps}}$ iff the image $\pi_R(\pi_I(\tilde{x})) = 0$ in $\mathbb{Z}^{|\mathbb{P}_R|}$. As proved in [77], for $s = gG \in \mathbb{P}$, the intersection pairing $\bullet : H^{\text{cusps}} \times H_{\text{cusps}} \rightarrow \mathbb{Z}$ gives

$$\{g(0), g(i\infty)\} \bullet x = \lambda_s - \lambda_{\sigma s}.$$

Thus, we write the intersection number as a function $\Delta_x : \mathbb{P} \rightarrow \mathbb{R}$ by

$$(2.7) \quad \Delta_x(s) = \lambda_s - \lambda_{\sigma s},$$

where x is given as above.

1.2. The modular complex. For x and y in \mathbb{H}^2 we denote by $\langle x, y \rangle$ the oriented geodesic arc connecting them. Moreover, in the decomposition $\text{PSL}(2, \mathbb{Z}) = \mathbb{Z}/2 * \mathbb{Z}/3$ as a free product, we denote by σ the generator of $\mathbb{Z}/2$ and by τ the generator of $\mathbb{Z}/3$.

DEFINITION 1.1. *The modular complex is the cell complex defined as follows.*

- *0-cells: the cusps $G \backslash \mathbb{P}^1(\mathbb{Q})$, and the elliptic points I and R .*
- *1-cells: the oriented geodesic arcs $G \backslash (\Gamma \cdot \langle i\infty, i \rangle)$ and $G \backslash (\Gamma \cdot \langle i, \rho \rangle)$, where by $\Gamma \cdot$ we mean the orbit under the action of Γ .*
- *2-cells: $G \backslash \{\Gamma \cdot E\}$, where E is the polygon with vertices $\{i, \rho, 1+i, i\infty\}$ and sides the corresponding geodesic arcs.*
- *Boundary operator: $\partial : C_2 \rightarrow C_1$ is given by*

$$gE \mapsto g\langle i, \rho \rangle + g\langle \rho, 1+i \rangle + g\langle 1+i, i\infty \rangle + g\langle i\infty, i \rangle,$$

for $g \in \Gamma$, and the boundary $\partial : C_1 \rightarrow C_0$ is given by

$$g\langle i\infty, i \rangle \mapsto g(i) - g(i\infty)$$

$$g\langle i, \rho \rangle \mapsto g(\rho) - g(i).$$

FIGURE 3. The cell decomposition of the modular complex

This gives a cell decomposition of \mathbb{H}^2 adapted to the action of $\mathrm{PSL}(2, \mathbb{Z})$ and congruence subgroups, *cf.* Figure 3.

We have the following result [68].

PROPOSITION 1.1. *The modular complex computes the first homology of $\overline{X_G}$:*

$$(2.8) \quad H_1(X_G) \cong \frac{\mathrm{Ker}(\partial : C_1 \rightarrow C_0)}{\mathrm{Im}(\partial : C_2 \rightarrow C_1)}.$$

We can derive versions of the modular complex that compute relative homology.

Notice that we have $\mathbb{Z}[\mathrm{cusps}] = C_0/\mathbb{Z}[R \cup I]$, hence the quotient complex

$$0 \rightarrow C_2 \xrightarrow{\partial} C_1 \xrightarrow{\tilde{\partial}} \mathbb{Z}[\mathrm{cusps}] \rightarrow 0,$$

with $\tilde{\partial}$ the induced boundary operator, computes the relative homology $H_1(\overline{X_G}, R \cup I)$. The cycles are given by $\mathbb{Z}[\mathbb{P}]$, as combinations of elements $g\langle i, \rho \rangle$, g ranging over representatives of \mathbb{P} , and by the elements $\oplus a_g \langle g(i\infty), g(i) \rangle$ satisfying $\sum a_g g(i\infty) = 0$. In fact, these can be represented as relative cycles in $(\overline{X_G}, R \cup I)$. Similarly, the subcomplex

$$0 \rightarrow \mathbb{Z}[\mathbb{P}] \xrightarrow{\partial} \mathbb{Z}[R \cup I] \rightarrow 0,$$

with $\mathbb{Z}[\mathbb{P}]$ generated by the elements $g\langle i, \rho \rangle$, computes the homology $H_1(\overline{X_G} - \mathrm{cusps})$. The homology

$$H_1(\overline{X_G} - \mathrm{cusps}, R \cup I) \cong \mathbb{Z}[\mathbb{P}]$$

is generated by the relative cycles $g\langle i, \rho \rangle$, g ranging over representatives of \mathbb{P} .

With the notation (2.4), we consider the groups $H_{R \cup I}^{\text{cusps}}$, $H_{\text{cusps}}^{R \cup I}$, H^{cusps} , and H_{cusps} .

We have a long exact sequence of relative homology

$$(2.9) \quad 0 \rightarrow H_{\text{cusps}} \rightarrow H_{\text{cusps}}^{R \cup I} \xrightarrow{(\tilde{\beta}_R, \tilde{\beta}_I)} H_0(R) \oplus H_0(I) \rightarrow \mathbb{Z} \rightarrow 0,$$

with H_{cusps} and $H_{\text{cusps}}^{R \cup I}$ as above, and with

$$\begin{aligned} H_0(I) &\cong \mathbb{Z}[\mathbb{P}_I], & \mathbb{P}_I &= \langle \sigma \rangle \backslash \mathbb{P} = G \backslash \tilde{I} \\ H_0(R) &\cong \mathbb{Z}[\mathbb{P}_R], & \mathbb{P}_R &= \langle \tau \rangle \backslash \mathbb{P} = G \backslash \tilde{R}, \end{aligned}$$

that is,

$$(2.10) \quad 0 \rightarrow H_{\text{cusps}} \rightarrow \mathbb{Z}[\mathbb{P}] \rightarrow \mathbb{Z}[\mathbb{P}_R] \oplus \mathbb{Z}[\mathbb{P}_I] \rightarrow \mathbb{Z} \rightarrow 0.$$

In the case of $H_{\text{cusps}}^{R \cup I}$ and $H_{R \cup I}^{\text{cusps}}$ the pairing (2.5) gives the identification of $\mathbb{Z}[\mathbb{P}]$ and $\mathbb{Z}^{|\mathbb{P}|}$, obtained by identifying the elements of \mathbb{P} with the corresponding delta functions. Thus, we can rewrite the sequence (2.10) as

$$(2.11) \quad 0 \rightarrow H^{\text{cusps}} \rightarrow \mathbb{Z}^{|\mathbb{P}|} \xrightarrow{(\beta_R, \beta_I)} \mathbb{Z}^{|\mathbb{P}_I|} \oplus \mathbb{Z}^{|\mathbb{P}_R|} \rightarrow \mathbb{Z} \rightarrow 0,$$

where $H_{R \cup I}^{\text{cusps}} \cong \mathbb{Z}^{|\mathbb{P}|}$.

In order to understand more explicitly the map (β_R, β_I) we give the following equivalent *algebraic* formulation of the modular complex (*cf.* [68] [77]).

The homology group $H_{\text{cusps}}^{R \cup I} = \mathbb{Z}[\mathbb{P}]$ is generated by the images in X_G of the geodesic segments $g\gamma_0 := g\langle i, \rho \rangle$, with g ranging over a chosen set of representatives of the coset space \mathbb{P} .

We can identify (*cf.* [77]) the dual basis δ_s of $H_{R \cup I}^{\text{cusps}} = \mathbb{Z}^{|\mathbb{P}|}$ with the images in X_G of the paths $g\eta_0$, where for a chosen point z_0 with $0 < \text{Re}(z_0) < 1/2$ and $|z_0| > 1$ the path η_0 is given by the geodesic arcs connecting ∞ to z_0 , z_0 to τz_0 , and τz_0 to 0 . These satisfy

$$\begin{aligned} [g\gamma_0] \bullet [g\eta_0] &= 1 \\ [g\gamma_0] \bullet [h\eta_0] &= 0, \end{aligned}$$

for $gG \neq hG$, under the intersection pairing (2.5)

Then, in the exact sequence (2.11), the identification of H^{cusps} with $\text{Ker}(\beta_R, \beta_I)$ is obtained by the identification $\{g(0), g(i\infty)\}_G \mapsto g\eta_0$, so that the relations imposed on the generators δ_s by the vanishing under β_I correspond to the relations $\delta_s \oplus \delta_{\sigma s}$ (or δ_s if $s = \sigma s$) and the vanishing under β_R gives another set of relations $\delta_s \oplus \delta_{\tau s} \oplus \delta_{\tau^2 s}$ (or δ_s if $s = \tau s$).

2. The noncommutative boundary of modular curves

The main idea that bridges between the algebro–geometric theory of modular curves and noncommutative geometry consists of replacing $\mathbb{P}^1(\mathbb{Q})$ in the classical compactification, which gives rise to a finite set of cusps, with $\mathbb{P}^1(\mathbb{R})$. This substitution cannot be done naively, since the quotient $G \backslash \mathbb{P}^1(\mathbb{R})$ is ill behaved topologically, as G does not act discretely on $\mathbb{P}^1(\mathbb{R})$.

When we regard the quotient $\Gamma \backslash \mathbb{P}^1(\mathbb{R})$, or more generally $\Gamma \backslash (\mathbb{P}^1(\mathbb{R}) \times \mathbb{P})$, itself as a noncommutative space, we obtain a geometric object that is rich enough to recover many important aspects of the classical theory of modular curves. In particular, it makes sense to study in terms of the geometry of such spaces the *limiting behavior* for certain arithmetic invariants defined on modular curves when $\tau \rightarrow \theta \in \mathbb{R} \setminus \mathbb{Q}$.

3. Modular interpretation: noncommutative elliptic curves

The boundary $\Gamma \backslash \mathbb{P}^1(\mathbb{R})$ of the modular curve $\Gamma \backslash \mathbb{H}^2$, viewed itself as a noncommutative space, continues to have a modular interpretation, as observed originally by Connes–Douglas–Schwarz ([25]). In fact, we can think of the quotients of S^1 by the action of rotations by an irrational angle (that is, the noncommutative tori) as particular degenerations of the classical elliptic curves, which are “invisible” to ordinary algebraic geometry. The quotient space $\Gamma \backslash \mathbb{P}^1(\mathbb{R})$ classifies these noncommutative tori up to Morita equivalence ([15], [85]) completes the moduli space $\Gamma \backslash \mathbb{H}^2$ of the classical elliptic curves. Thus, from a conceptual point of view it is reasonable to think of $\Gamma \backslash \mathbb{P}^1(\mathbb{R})$ as the boundary of $\Gamma \backslash \mathbb{H}^2$, when we allow points in this classical moduli space (that is, elliptic curves) to have non-classical degenerations to noncommutative tori.

Noncommutative tori are, in a sense, a prototype example of noncommutative spaces, in as one can see there displayed the full range of techniques of noncommutative geometry (*cf.* [15], [17]). As C^* -algebras, noncommutative tori are *irrational rotation algebras*. We recall some basic properties of noncommutative tori, which justify the claim that these algebras behave like a noncommutative version of elliptic curves. We follow mostly [15] [20] and [85] for this material.

3.1. Irrational rotation and Kronecker foliation.

DEFINITION 3.1. *The irrational rotation algebra \mathcal{A}_θ , for a given $\theta \in \mathbb{R}$, is the universal C^* -algebra $C^*(U, V)$, generated by two unitary operators U and V , subject to the commutation relation*

$$(2.12) \quad UV = e^{2\pi i \theta} VU.$$

The algebra A_θ can be realized as a subalgebra of bounded operators on the Hilbert space $\mathcal{H} = L^2(S^1)$, with the circle $S^1 \cong \mathbb{R}/\mathbb{Z}$. For a given $\theta \in \mathbb{R}$, we consider two operators, that act on a complete orthonormal basis e_n of \mathcal{H} as

$$(2.13) \quad Ue_n = e_{n+1}, \quad Ve_n = e^{2\pi i n \theta} e_n.$$

It is easy to check that these operators satisfy the commutation relation (2.12), since, for any $f \in \mathcal{H}$ we have $VUf(t) = Uf(t - \theta) = e^{2\pi i(t-\theta)} f(t - \theta)$, while $UVf(t) = e^{2\pi i t} f(t - \theta)$.

The irrational rotation algebra be described in more geometric terms by the foliation on the usual commutative torus by lines with irrational slope. On $T^2 = \mathbb{R}^2/\mathbb{Z}^2$ one considers the foliation $dx = \theta dy$, for $x, y \in \mathbb{R}/\mathbb{Z}$. The space of leaves is described as $X = \mathbb{R}/(\mathbb{Z} + \theta\mathbb{Z}) \simeq S^1/\theta\mathbb{Z}$. This quotient is ill behaved as a classical topological space, hence it cannot be well described by ordinary geometry.

A transversal to the foliation is given for instance by the choice $T = \{y = 0\}$, $T \cong S^1 \cong \mathbb{R}/\mathbb{Z}$. Then the non-commutative torus is obtained (cf. [15] [20]) as

$$(2.14) \quad \mathcal{A}_\theta = \{(f_{ab}) \mid a, b \in T \text{ in the same leaf } \}$$

where (f_{ab}) is a power series $b = \sum_{n \in \mathbb{Z}} b_n V^n$ and each b_n is an element of the algebra $C(S^1)$. The multiplication is given by

$$VhV^{-1} = h \circ R_\theta^{-1},$$

with

$$R_\theta x = x + \theta \pmod{1}.$$

The algebra $C(S^1)$ is generated by $U(t) = e^{2\pi i t}$, hence we recover the generating system (U, V) with the relation

$$UV = e^{2\pi i \theta} VU.$$

What we have obtained through this description is an identification of the irrational rotation algebra of Definition 3.1 with the crossed product C^* -algebra

$$(2.15) \quad \mathcal{A}_\theta = C(S^1) \rtimes_{R_\theta} \mathbb{Z}$$

representing the quotient $S^1/\theta\mathbb{Z}$ as a non-commutative space.

3.2. Degenerations of elliptic curves. An elliptic curve E_τ over \mathbb{C} can be described as the quotient $E_\tau = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ of the complex plane by a 2-dimensional lattice $\Lambda = \mathbb{Z} + \tau\mathbb{Z}$, where we can take $\Im(\tau) > 0$. It is also possible to describe the elliptic curve E_q , for $q \in \mathbb{C}^*$, $q = \exp(2\pi i \tau)$, $|q| < 1$, in terms of its Jacobi uniformization, namely

FIGURE 4. The fundamental domain for the Jacobi uniformization of the elliptic curve

as the quotient of \mathbb{C}^* by the action of the group generated by a single hyperbolic element in $PSL(2, \mathbb{C})$,

$$(2.16) \quad E_q = \mathbb{C}^*/q^{\mathbb{Z}}.$$

The fundamental domain for the action of $q^{\mathbb{Z}}$ is an annulus

$$\{z \in \mathbb{C} : |q| < z \leq 1\}$$

of radii 1 and $|q|$, and the identification of the two boundary circles is obtained via the combination of scaling and rotation given by multiplication by q .

Now let us consider a degeneration where $q \rightarrow \exp(2\pi i\theta) \in S^1$, with $\theta \in \mathbb{R} \setminus \mathbb{Q}$. We can say heuristically that in this degeneration the elliptic curve becomes a non-commutative torus

$$E_q \implies \mathcal{A}_\theta,$$

in the sense that, as we let $q \rightarrow \exp(2\pi i\theta)$, the annulus of the fundamental domain shrinks to a circle S^1 and we are left with a quotient of S^1 by the infinite cyclic group generated by the irrational rotation $\exp(2\pi i\theta)$. Since this quotient is ill behaved as a classical quotient, such degenerations do not admit a description within the context of classical geometry. However, when we replace the quotient by the corresponding crossed product algebra $C(S^1) \rtimes_\theta \mathbb{Z}$ we find the irrational rotation algebra of definition 3.1. Thus, we can consider such algebras as non-commutative (degenerate) elliptic curves.

More precisely, when one considers degenerations of elliptic curves $E_\tau = \mathbb{C}^*/q^\mathbb{Z}$ for $q = e^{2\pi i\tau}$, what one obtains in the limit is the suspension of a noncommutative torus. In fact, as the parameter q degenerates to a point on the unit circle, $q \rightarrow e^{2\pi i\theta}$, the “nice” quotient $E_\tau = \mathbb{C}^*/q^\mathbb{Z}$ degenerates to the “bad” quotient $E_\theta = \mathbb{C}^*/e^{2\pi i\tau\mathbb{Z}}$, whose noncommutative algebra of coordinates is Morita equivalent $\mathcal{A}_\theta \otimes C_0(\mathbb{R})$, with $\rho \in \mathbb{R}$ the radial coordinate $\mathbb{C}^* \ni z = e^\rho e^{2\pi is}$.

Because of the Thom isomorphism [16], the K-theory of the noncommutative space $E_\theta = C_0(\mathbb{R}^2) \rtimes (\mathbb{Z}\theta + \mathbb{Z})$ satisfies

$$(2.17) \quad K_0(E_\theta) = K_1(\mathcal{A}_\theta) \quad \text{and} \quad K_1(E_\theta) = K_0(\mathcal{A}_\theta),$$

which is again compatible with the identification of the E_θ (rather than \mathcal{A}_θ) as degenerations of elliptic curves. In fact, for instance, the Hodge filtration on the H^1 of an elliptic curve and the equivalence between the elliptic curve and its Jacobian, have analogs for the noncommutative torus \mathcal{A}_θ in terms of the filtration on HC^0 induced by the inclusion of K_0 (cf. [17] p. 132–139, [23] §XIII), while by the Thom isomorphism, these would again appear on the HC^1 in the case of the “noncommutative elliptic curve” E_θ .

The point of view of degenerations is sometimes a useful guideline. For instance, one can study the limiting behavior of arithmetic invariants defined on the parameter space of elliptic curves (on modular curves), in the limit when $\tau \rightarrow \theta \in \mathbb{R} \setminus \mathbb{Q}$. An instance of this type of result is the theory of limiting modular symbols of [70].

3.3. Morita equivalent NC tori. To extend the modular interpretation of the quotient $\Gamma \backslash \mathbb{H}^2$ as moduli of elliptic curves to the noncommutative boundary $\Gamma \backslash \mathbb{P}^1(\mathbb{R})$, one needs to check that points in the same orbit of the action of the modular group $\text{PSL}(2, \mathbb{Z})$ by fractional linear transformations on $\mathbb{P}^1(\mathbb{R})$ define equivalent noncommutative tori, where equivalence here is to be understood in the Morita sense.

Connes showed in [15] (cf. also [85]) that the noncommutative tori \mathcal{A}_θ and $\mathcal{A}_{-1/\theta}$ are Morita equivalent. Geometrically in terms of the Kronecker foliation and the description (2.14) of the corresponding algebras, the Morita equivalence $\mathcal{A}_\theta \simeq \mathcal{A}_{-1/\theta}$ corresponds to changing the choice of the transversal from $T = \{y = 0\}$ to $T' = \{x = 0\}$.

In fact, all Morita equivalences arise in this way, by changing the choice of the transversal of the foliation, so that \mathcal{A}_θ and $\mathcal{A}_{\theta'}$ are Morita equivalent if and only if $\theta \sim \theta'$, under the action of $\text{PSL}(2, \mathbb{Z})$.

Connes constructed in [15] explicit bimodules realizing the Morita equivalences between non-commutative tori \mathcal{A}_θ and $\mathcal{A}_{\theta'}$ with

$$\theta' = \frac{a\theta + b}{c\theta + d} = g\theta,$$

for

$$g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma,$$

by taking $\mathcal{M}_{\theta, \theta'}$ to be the Schwartz space $\mathcal{S}(\mathbb{R} \times \mathbb{Z}/c)$, with the right action of \mathcal{A}_θ

$$Uf(x, u) = f\left(x - \frac{c\theta + d}{c}, u - 1\right)$$

$$Vf(x, u) = \exp(2\pi i(x - ud/c))f(x, u)$$

and the left action of $\mathcal{A}_{\theta'}$

$$U'f(x, u) = f\left(x - \frac{1}{c}, u - a\right)$$

$$V'f(x, u) = \exp\left(2\pi i\left(\frac{x}{c\theta + d} - \frac{u}{c}\right)\right)f(x, u).$$

3.4. Other properties of NC elliptic curves. There are other ways in which the irrational rotation algebra behaves much like an elliptic curve, most notably the relation between the elliptic curve and its Jacobian (*cf.* [17] and [23]) and some aspects of the theory of theta functions, which we recall briefly.

The commutative torus $T^2 = S^1 \times S^1$ is connected, hence the algebra $C(T^2)$ does not contain interesting projections. On the contrary, the noncommutative tori \mathcal{A}_θ contain a large family of nontrivial projections. Rieffel in [85] showed that, for a given θ irrational and for all $\alpha \in (\mathbb{Z} \oplus \mathbb{Z}\theta) \cap [0, 1]$, there exists a projection P_α in \mathcal{A}_θ , with $\text{Tr}(P_\alpha) = \alpha$. A different construction of projections in \mathcal{A}_θ , given by Boca [7], has arithmetic relevance, in as these projections correspond to the theta functions for noncommutative tori defined by Manin in [64].

A method of constructing projections in C^* -algebras is based on the following two steps (*cf.* [85] and [63]):

- (1) Suppose given a bimodule ${}_{\mathcal{A}}\mathcal{M}_{\mathcal{B}}$. If an element $\xi \in {}_{\mathcal{A}}\mathcal{M}_{\mathcal{B}}$ admits an invertible $*$ -invariant square root $\langle \xi, \xi \rangle_{\mathcal{B}}^{1/2}$, then the element $\mu := \xi \langle \xi, \xi \rangle_{\mathcal{B}}^{-1/2}$ satisfies $\mu \langle \mu, \mu \rangle_{\mathcal{B}} = \mu$.
- (2) Let $\mu \in {}_{\mathcal{A}}\mathcal{M}_{\mathcal{B}}$ be a non-trivial element such that $\mu \langle \mu, \mu \rangle_{\mathcal{B}} = \mu$. Then the element $P := {}_{\mathcal{A}} \langle \mu, \mu \rangle$ is a projection.

In Boca's construction, one obtains elements ξ from Gaussian elements in some Heisenberg modules, in such a way that the corresponding $\langle \xi, \xi \rangle_{\mathcal{B}}$ is a *quantum theta function* in the sense of Manin [64]. An introduction to the relation between the Heisenberg groups and the theory of theta functions is given in the third volume of Mumford's Tata lectures on theta, [79].

4. Limiting modular symbols

We consider the action of the group $\Gamma = \mathrm{PGL}(2, \mathbb{Z})$ on the upper and lower half planes \mathbb{H}^{\pm} and the modular curves defined by the quotient $X_G = G \backslash \mathbb{H}^{\pm}$, for G a finite index subgroup of Γ . Then the noncommutative compactification of the modular curves is obtained by extending the action of Γ on \mathbb{H}^{\pm} to the action on the full

$$\mathbb{P}^1(\mathbb{C}) = \mathbb{H}^{\pm} \cup \mathbb{P}^1(\mathbb{R}),$$

so that we have

$$(2.18) \quad \overline{X}_G = G \backslash \mathbb{P}^1(\mathbb{C}) = \Gamma \backslash (\mathbb{P}^1(\mathbb{C}) \times \mathbb{P}).$$

Due to the fact that Γ does not act discretely on $\mathbb{P}^1(\mathbb{R})$, the quotient (2.18) makes sense as a noncommutative space

$$(2.19) \quad C(\mathbb{P}^1(\mathbb{C}) \times \mathbb{P}) \rtimes \Gamma.$$

Here $\mathbb{P}^1(\mathbb{R}) \subset \mathbb{P}^1(\mathbb{C})$ is the *limit set* of the group Γ , namely the set of accumulation points of orbits of elements of Γ on $\mathbb{P}^1(\mathbb{C})$. We will see another instance of noncommutative geometry arising from the action of a group of Möbius transformations of $\mathbb{P}^1(\mathbb{C})$ on its limit set, in the context of the geometry at the archimedean primes of arithmetic varieties.

4.1. Generalized Gauss shift and dynamics. We have described the boundary of modular curves by the crossed product C^* -algebra

$$(2.20) \quad C(\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}) \rtimes \Gamma.$$

We can also describe the quotient space $\Gamma \backslash (\mathbb{P}^1(\mathbb{R}) \times \mathbb{P})$ in the following equivalent way. If $\Gamma = \mathrm{PGL}(2, \mathbb{Z})$, then Γ -orbits in $\mathbb{P}^1(\mathbb{R})$ are the same as equivalence classes of points of $[0, 1]$ under the equivalence relation

$$x \sim_T y \Leftrightarrow \exists n, m : T^n x = T^m y$$

where $Tx = 1/x - [1/x]$ is the classical Gauss shift of the continued fraction expansion. Namely, the equivalence relation is that of having the same tail of the continued fraction expansion (shift-tail equivalence).

A simple generalization of this classical result yields the following.

LEMMA 4.1. Γ orbits in $\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}$ are the same as equivalence classes of points in $[0, 1] \times \mathbb{P}$ under the equivalence relation

$$(2.21) \quad (x, s) \sim_T (y, t) \Leftrightarrow \exists n, m : T^n(x, s) = T^m(y, t)$$

where $T : [0, 1] \times \mathbb{P} \rightarrow [0, 1] \times \mathbb{P}$ is the shift

$$(2.22) \quad T(x, s) = \left(\frac{1}{x} - \left[\frac{1}{x} \right], \left(\begin{array}{cc} -[1/x] & 1 \\ 1 & 0 \end{array} \right) \cdot s \right)$$

generalizing the classical shift of the continued fraction expansion.

As a noncommutative space, the quotient by the equivalence relation (2.21) is described by the C^* -algebra of the groupoid of the equivalence relation

$$\mathcal{G}([0, 1] \times \mathbb{P}, T) = \{((x, s), m - n, (y, t)) : T^m(x, s) = T^n(y, t)\}$$

with objects $\mathcal{G}^0 = \{((x, s), 0, (x, s))\}$.

In fact, for any T -invariant subset $E \subset [0, 1] \times \mathbb{P}$, we can consider the equivalence relation (2.21). The corresponding groupoid C^* -algebra $C^*(\mathcal{G}(E, T))$ encodes the dynamical properties of the map T on E .

Geometrically, the equivalence relation (2.21) on $[0, 1] \times \mathbb{P}$ is related to the action of the geodesic flow on the horocycle foliation on the modular curves.

4.2. Arithmetic of modular curves and noncommutative boundary. The result of Lemma 4.1 shows that the properties of the dynamical system T or (2.21) can be used to describe the geometry of the noncommutative boundary of modular curves. There are various types of results that can be obtained by this method ([70] [71]), which we will discuss in the rest of this chapter.

- (1) Using the properties of this dynamical system it is possible to recover and enrich the theory of modular symbols on X_G , by extending the notion of modular symbols from geodesics connecting cusps to images of geodesics in \mathbb{H}^2 connecting irrational points on the boundary $\mathbb{P}^1(\mathbb{R})$. In fact, the irrational points of $\mathbb{P}^1(\mathbb{R})$ define *limiting modular symbols*. In the case of quadratic irrationalities, these can be expressed in terms of the classical modular symbols and recover the generators of the homology of the classical compactification by cusps $\overline{X_G}$. In the remaining cases, the limiting modular symbols vanishes almost everywhere.
- (2) It is possible to reinterpret Dirichlet series related to modular forms of weight 2 in terms of integrals on $[0, 1]$ of certain intersection numbers obtained from homology classes defined

in terms of the dynamical system. In fact, even when the limiting modular symbol vanishes, it is possible to associate a non-trivial cohomology class in X_G to irrational points on the boundary, in such a way that an average of the corresponding intersection numbers give Mellin transforms of modular forms of weight 2 on X_G .

- (3) The Selberg zeta function of the modular curve can be expressed as a Fredholm determinant of the Perron-Frobenius operator associated to the dynamical system on the “boundary”.
- (4) Using the first formulation of the boundary as the noncommutative space (2.20) we can obtain a canonical identification of the modular complex with a sequence of K-groups of the C^* -algebra. The resulting exact sequence for K-groups can be interpreted, using the description (2.21) of the quotient space, in terms of the Baum–Connes assembly map and the Thom isomorphism.

All this shows that the noncommutative space $C(\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}) \rtimes \Gamma$, which we have so far considered as a boundary stratum of $C(\mathbb{H}^2 \times \mathbb{P}) \rtimes \Gamma$, in fact contains a good part of the arithmetic information on the classical modular curve itself. The fact that information on the “bulk space” is stored in its boundary at infinity can be seen as an instance of the physical principle of holography (bulk/boundary correspondence) in string theory (*cf.* [69]). We will discuss the holography principle more in details in relation to the geometry of the archimedean fibers of arithmetic varieties.

4.3. Limiting modular symbols. Let γ_β be an infinite geodesic in the hyperbolic plane \mathbb{H} with one end at $i\infty$ and the other end at $\beta \in \mathbb{R} \setminus \mathbb{Q}$. Let $x \in \gamma_\beta$ be a fixed base point, τ be the geodesic arc length, and $y(\tau)$ be the point along γ_β at a distance τ from x , towards the end β . Let $\{x, y(\tau)\}_G$ denote the homology class in X_G determined by the image of the geodesic arc $\langle x, y(\tau) \rangle$ in \mathbb{H} .

DEFINITION 4.1. *The limiting modular symbol is defined as*

$$(2.23) \quad \{\{*, \beta\}\}_G := \lim_{\tau} \frac{1}{\tau} \{x, y(\tau)\}_G \in H_1(X_G, \mathbb{R}),$$

whenever such limit exists.

The limit (2.23) is independent of the choice of the initial point x as well as of the choice of the geodesic in \mathbb{H} ending at β , as discussed in [70] (*cf.* Figure 5). We use the notation $\{\{*, \beta\}\}_G$ as introduced in

[70], where $*$ in the first argument indicates the independence on the choice of x , and the double brackets indicate the fact that the homology class is computed as a limiting cycle.

4.3.1. *Dynamics of continued fractions.* As above, we consider on $[0, 1] \times \mathbb{P}$ the dynamical system

$$(2.24) \quad T : [0, 1] \times \mathbb{P} \rightarrow [0, 1] \times \mathbb{P} \\ T(\beta, t) = \left(\frac{1}{\beta} - \left[\frac{1}{\beta} \right], \left(\begin{array}{cc} -[1/\beta] & 1 \\ 1 & 0 \end{array} \right) \cdot t \right).$$

This generalizes the classical shift map of the continued fraction

$$T : [0, 1] \rightarrow [0, 1] \quad T(x) = \frac{1}{x} - \left[\frac{1}{x} \right].$$

Recall the following basic notation regarding continued fraction expansion. Let k_1, \dots, k_n be independent variables and, for $n \geq 1$, let

$$[k_1, \dots, k_n] := \frac{1}{k_1 + \frac{1}{k_2 + \dots + \frac{1}{k_n}}} = \frac{P_n(k_1, \dots, k_n)}{Q_n(k_1, \dots, k_n)}.$$

The P_n, Q_n are polynomials with integral coefficients, which can be calculated inductively from the relations

$$Q_{n+1}(k_1, \dots, k_n, k_{n+1}) = k_{n+1}Q_n(k_1, \dots, k_n) + Q_{n-1}(k_1, \dots, k_{n-1}), \\ P_n(k_1, \dots, k_n) = Q_{n-1}(k_2, \dots, k_n),$$

with $Q_{-1} = 0, Q_0 = 1$. Thus, we obtain

$$\begin{aligned} & [k_1, \dots, k_{n-1}, k_n + x_n] \\ &= \frac{P_{n-1}(k_1, \dots, k_{n-1})x_n + P_n(k_1, \dots, k_n)}{Q_{n-1}(k_1, \dots, k_{n-1})x_n + Q_n(k_1, \dots, k_n)} = \begin{pmatrix} P_{n-1} & P_n \\ Q_{n-1} & Q_n \end{pmatrix} (x_n), \end{aligned}$$

with the standard matrix notation for fractional linear transformations,

$$z \mapsto \frac{az + b}{cz + d} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} (z).$$

If $\alpha \in (0, 1)$ is an irrational number, there is a unique sequence of integers $k_n(\alpha) \geq 1$ such that α is the limit of $[k_1(\alpha), \dots, k_n(\alpha)]$ as $n \rightarrow \infty$. Moreover, there is a unique sequence $x_n(\alpha) \in (0, 1)$ such that

$$\alpha = [k_1(\alpha), \dots, k_{n-1}(\alpha), k_n(\alpha) + x_n(\alpha)]$$

for each $n \geq 1$. We obtain

$$\alpha = \begin{pmatrix} 0 & 1 \\ 1 & k_1(\alpha) \end{pmatrix} \cdots \begin{pmatrix} 0 & 1 \\ 1 & k_n(\alpha) \end{pmatrix} (x_n(\alpha)).$$

We set

$$p_n(\alpha) := P_n(k_1(\alpha), \dots, k_n(\alpha)), \quad q_n(\alpha) := Q_n(k_1(\alpha), \dots, k_n(\alpha))$$

so that $p_n(\alpha)/q_n(\alpha)$ is the sequence of convergents to α . We also set

$$g_n(\alpha) := \begin{pmatrix} p_{n-1}(\alpha) & p_n(\alpha) \\ q_{n-1}(\alpha) & q_n(\alpha) \end{pmatrix} \in \mathrm{GL}(2, \mathbb{Z}).$$

Written in terms of the continued fraction expansion, the shift T is given by

$$T : [k_0, k_1, k_2, \dots] \mapsto [k_1, k_2, k_3, \dots].$$

The properties of the shift (2.24) can be used to extend the notion of modular symbols to geodesics with irrational ends ([70]). Such geodesics correspond to infinite geodesics on the modular curve X_G , which exhibit a variety of interesting possible behaviors, from closed geodesics to geodesics that approximate some limiting cycle, to geodesics that wind around different homology class exhibiting a typically chaotic behavior.

4.3.2. Lyapunov spectrum. A measure of how chaotic a dynamical system is, or better of how fast nearby orbits tend to diverge, is given by the Lyapunov exponent.

DEFINITION 4.2. *the Lyapunov exponent of $T : [0, 1] \rightarrow [0, 1]$ is defined as*

$$(2.25) \quad \lambda(\beta) := \lim_{n \rightarrow \infty} \frac{1}{n} \log |(T^n)'(\beta)| = \lim_{n \rightarrow \infty} \frac{1}{n} \log \prod_{k=0}^{n-1} |T'(T^k \beta)|.$$

The function $\lambda(\beta)$ is T -invariant. Moreover, in the case of the classical continued fraction shift $T\beta = 1/\beta - [1/\beta]$ on $[0, 1]$, the Lyapunov exponent is given by

$$(2.26) \quad \lambda(\beta) = 2 \lim_{n \rightarrow \infty} \frac{1}{n} \log q_n(\beta),$$

with $q_n(\beta)$ the successive denominators of the continued fraction expansion.

In particular, the Khintchine–Lévy theorem shows that, for almost all β 's (with respect to the Lebesgue measure on $[0, 1]$) the limit (2.26) is equal to

$$(2.27) \quad \lambda(\beta) = \pi^2 / (6 \log 2) =: \lambda_0.$$

There is, however, an exceptional set in $[0, 1]$ of Hausdorff dimension $\dim_H = 1$ but with Lebesgue measure zero where limit defining the Lyapunov exponent does not exist.

As we will see later, in “good cases” the value $\lambda(\beta)$ can be computed from the spectrum of Perron–Frobenius operator of the shift T .

The *Lyapunov spectrum* is introduced (cf. [83]) by decomposing the unit interval in level sets of the Lyapunov exponent $\lambda(\beta)$ of (2.25). Let $L_c = \{\beta \in [0, 1] \mid \lambda(\beta) = c \in \mathbb{R}\}$. These sets provide a T -invariant decomposition of the unit interval,

$$[0, 1] = \bigcup_{c \in \mathbb{R}} L_c \cup \{\beta \in [0, 1] \mid \lambda(\beta) \text{ does not exist}\}.$$

These level sets are uncountable dense T -invariant subsets of $[0, 1]$, of varying Hausdorff dimension [83]. The Lyapunov spectrum measures how the Hausdorff dimension varies, as a function $h(c) = \dim_H(L_c)$.

4.3.3. *Limiting modular symbols and iterated shifts.* We introduce a function $\varphi : \mathbb{P} \rightarrow H^{\text{cusps}}$ of the form

$$(2.28) \quad \varphi(s) = \{g(0), g(i\infty)\}_G,$$

where $g \in \text{PGL}(2, \mathbb{Z})$ (or $\text{PSL}(2, \mathbb{Z})$) is a representative of the coset $s \in \mathbb{P}$.

Then we can compute the limit (2.23) in the following way.

THEOREM 4.2. *Consider a fixed $c \in \mathbb{R}$ which corresponds to some level set L_c of the Lyapunov exponent (2.26). Then, for all $\beta \in L_c$, the limiting modular symbol (2.23) is computed by the limit*

$$(2.29) \quad \lim_{n \rightarrow \infty} \frac{1}{cn} \sum_{k=1}^n \varphi \circ T^k(t_0),$$

where T is the shift of (2.24) and $t_0 \in \mathbb{P}$.

Without loss of generality, one can consider the geodesic γ_β in $\mathbb{H} \times \mathbb{P}$ with one end at $(i\infty, t_0)$ and the other at (β, t_0) , for $\varphi(t_0) = \{0, i\infty\}_G$.

The argument given in §2.3 of [70] is based on the fact that one can replace the homology class defined by the vertical geodesic with one obtained by connecting the successive rational approximations to β in the continued fraction expansion (Figure 5). Namely, one can replace the path $\langle x_0, y_n \rangle$ with the union of arcs

$$\langle x_0, y_0 \rangle \cup \langle y_0, p_0/q_0 \rangle \cup \bigcup_{k=1}^n \langle p_{k-1}/q_{k-1}, p_k/q_k \rangle \cup \langle p_n/q_n, y_n \rangle$$

FIGURE 5. Geodesics defining limiting modular symbols

representing the same homology class in $H_1(\overline{X}_G, \mathbb{Z})$.

The result then follows by estimating the geodesic distance $\tau \sim -\log \Im y + O(1)$, as $y(\tau) \rightarrow \beta$ and

$$\frac{1}{2q_n q_{n+1}} < \Im y_n < \frac{1}{2q_n q_{n-1}},$$

where y_n is the intersection of γ_β and the geodesic with ends at $p_{n-1}(\beta)/q_{n-1}(\beta)$ and $p_n(\beta)/q_n(\beta)$.

The matrix $g_k^{-1}(\beta)$, with

$$g_k(\beta) = \begin{pmatrix} p_{k-1}(\beta) & p_k(\beta) \\ q_{k-1}(\beta) & q_k(\beta) \end{pmatrix},$$

acts on points $(\beta, t) \in [0, 1] \times \mathbb{P}$ as the k -th power of the shift map T of (2.24). Thus, we obtain

$$\varphi(T^k t_0) = \{g_k^{-1}(\beta)(0), g_k^{-1}(\beta)(i\infty)\}_G = \left\{ \frac{p_{k-1}(\beta)}{q_{k-1}(\beta)}, \frac{p_k(\beta)}{q_k(\beta)} \right\}_G.$$

4.4. Ruelle and Perron–Frobenius operators. A general principle in the theory of dynamical systems is that one can often study the dynamical properties of a map T (*e.g.* ergodicity) via the spectral theory of an associated operator. This allows one to employ techniques of functional analysis and derive conclusions on dynamics.

In our case, to the shift map T of (2.24), we associate the operator

$$(2.30) \quad (L_\sigma f)(x, t) = \sum_{k=1}^{\infty} \frac{1}{(x+k)^{2\sigma}} f\left(\frac{1}{x+k}, \begin{pmatrix} 0 & 1 \\ 1 & k \end{pmatrix} \cdot t\right)$$

depending on a complex parameter σ .

More generally, the Ruelle transfer operator of a map T is defined as

$$(2.31) \quad (L_\sigma f)(x, t) = \sum_{(y, s) \in T^{-1}(x, t)} \exp(h(y, s)) f(y, s),$$

where we take $h(x, t) = -2\sigma \log |T'(x, t)|$. Clearly this operator is well suited for capturing the dynamical properties of the map T as it is defined as a weighted sum over preimages. On the other hand, there is another operator that can be associated to a dynamical system and which typically has better spectral properties, but is less clearly related to the dynamics. The best circumstances are when these two agree (for a particular value of the parameter). The other operator is the Perron–Frobenius operator \mathcal{P} . This is defined by the relation

$$(2.32) \quad \int_{[0,1] \times \mathbb{P}} f(g \circ T) d\mu_{Leb} = \int_{[0,1] \times \mathbb{P}} (\mathcal{P} f) g d\mu_{Leb}.$$

In the case of the shift T of (2.24) we have in fact that

$$\mathcal{P} = L_\sigma|_{\sigma=1}.$$

4.4.1. *Spectral theory of L_1 .* In the case of the modular group $G = \Gamma$, the spectral theory of the Perron Frobenius operator of the Gauss shift was studied by D.Mayer [75]. More recently, Chang and Mayer [13] extended the results to the case of congruence subgroups. A similar approach is used in [70] to study the properties of the shift (2.24).

The Perron–Frobenius operator

$$(L_1 f)(x, s) = \sum_{k=1}^{\infty} \frac{1}{(x+k)^2} f\left(\frac{1}{x+k}, \begin{pmatrix} 0 & 1 \\ 1 & k \end{pmatrix} \cdot s\right)$$

for the shift (2.24) has the following properties.

THEOREM 4.3. *On a Banach space of holomorphic functions on $D \times \mathbb{P}$ continuous to boundary, with $D = \{z \in \mathbb{C} \mid |z-1| < 3/2\}$, under the condition (irreducibility)*

$$(2.33) \quad \mathbb{P} = \cup_{n=0}^{\infty} \left\{ \begin{pmatrix} 0 & 1 \\ 1 & k_1 \end{pmatrix} \cdots \begin{pmatrix} 0 & 1 \\ 1 & k_n \end{pmatrix} (t_0) \mid k_1, \dots, k_n \geq 1 \right\},$$

the Perron–Frobenius operator L_1 has the following properties:

- L_1 is a nuclear operator, of trace class.
- L_1 has top eigenvalue $\lambda = 1$. This eigenvalue is simple. The corresponding eigenfunction is (up to normalization)

$$\frac{1}{(1+x)}.$$

- The rest of the spectrum of L_1 is contained in a ball of radius $r < 1$.
- There is a complete set of eigenfunctions.

The irreducibility condition (2.33) is satisfied by congruence subgroups.

For other T -invariant subsets $E \subset [0, 1] \times \mathbb{P}$, one can also consider operators $L_{E,\sigma}$ and \mathcal{P}_E . When the set has the property that $\mathcal{P}_E = L_{E,\delta_E}$, for $\delta_E = \dim_H E$ the Hausdorff dimension, one can use the spectral theory of the operator \mathcal{P}_E to study the dynamical properties of T .

The Lyapunov exponent can be read off the spectrum of the family of operators $L_{E,\sigma}$.

LEMMA 4.4. *Let λ_σ denote the top eigenvalue of $L_{E,\sigma}$. Then*

$$\lambda(\beta) = \frac{d}{d\sigma} \lambda_\sigma|_{\sigma=\dim_H(E)} \quad \mu_H \text{ a.e. in } E$$

4.4.2. *The Gauss problem.* Let

$$(2.34) \quad m_n(x) := \text{measure of } \{\alpha \in (0, 1) \mid x_n(\alpha) \leq x\}$$

with $\alpha = [a_1(\alpha), \dots, a_{n-1}(\alpha), a_n(\alpha) + x_n(\alpha)]$.

The asymptotic behavior of the measures m_n is a famous problem on the distribution of continued fractions formulated by Gauss, who conjectured that

$$(2.35) \quad m(x) = \lim_{n \rightarrow \infty} m_n(x) \stackrel{?}{=} \frac{1}{\log 2} \log(1+x).$$

The convergence of (2.34) to (2.35) was only proved by R. Kuzmin in 1928. Other proofs were then given by P. Lévy (1929), K. Babenko (1978) and D. Mayer (1991). The arguments used by Babenko and Mayer use the spectral theory on the Perron–Frobenius operator. Of these different arguments only the latter extends nicely to the case of the generalized Gauss shift (2.24).

The Gauss problem can be formulated in terms of a recursive relation

$$(2.36) \quad m'_{n+1}(x) = (L_1 m'_n)(x) := \sum_{k=1}^{\infty} \frac{1}{(x+k)^2} m'_n\left(\frac{1}{x+k}\right).$$

The right hand side of (2.36) is the image of m'_n under the Gauss–Kuzmin operator. This is nothing but the Perron–Frobenius operator for the shift T in the case of the group $\Gamma = \text{PGL}(2, \mathbb{Z})$.

As a consequence of Theorem 4.3, one obtains the following result.

THEOREM 4.5. *Let*

$$m_n(x, t) := \mu_{Leb}\{(y, s) : x_n(y) \leq x, g_n(y)^{-1}(s) = t\}.$$

Then we have

- $m'_n(x, t) = L_1^n(1)$.
- *The limit $m(x, t) = \lim_{n \rightarrow \infty} m_n(x, t)$ exists and equals*

$$m(x, t) = \frac{1}{|\mathbb{P}| \log 2} \log(1 + x).$$

This shows that there exists a unique T -invariant measure on $[0, 1] \times \mathbb{P}$. This is uniform in the discrete set \mathbb{P} (the counting measure) and it is the Gauss measure of the shift of the continued fraction expansion on $[0, 1]$.

4.5. Two theorems on limiting modular symbols. The result on the T -invariant measure allows us to study the general behavior of limiting modular symbols.

A special role is played by limiting modular symbols $\{\{*, \beta\}\}$ where β is a quadratic irrationality in $\mathbb{R} \setminus \mathbb{Q}$.

THEOREM 4.6. *Let $g \in G$ be hyperbolic, with eigenvalue Λ_g corresponding to the attracting fixed point α_g^+ . Let $\Lambda(g) := |\log \Lambda_g|$, and let ℓ be the period of the continued fraction expansion of $\beta = \alpha_g^+$. Then*

$$\begin{aligned} \{\{*, \beta\}\}_G &= \frac{\{0, g(0)\}_G}{\Lambda(g)} \\ &= \frac{1}{\lambda(\beta)\ell} \sum_{k=1}^{\ell} \{g_k^{-1}(\beta) \cdot 0, g_k^{-1}(\beta) \cdot i\infty\}_G. \end{aligned}$$

This shows that, in this case, the limiting modular symbols are linear combinations of classical modular symbols, with coefficients in the field generated over \mathbb{Q} by the Lyapunov exponents $\lambda(\beta)$ of the quadratic irrationalities.

In terms of geodesics on the modular curve, this is the case where the geodesic has a limiting cycle given by the closed geodesic $\{0, g(0)\}_G$ (Figure 6).

There is then the “generic case”, where, contrary to the previous example, the geodesics wind around many different cycles in such a way that the resulting homology class averages out to zero over long distances (Figure 7).

FIGURE 6. Limiting modular symbols: limiting cycle

FIGURE 7. Limiting modular symbols: chaotic tangling and untangling

THEOREM 4.7. *For a T -invariant $E \subset [0, 1] \times \mathbb{P}$, under the irreducibility condition for E ,*

$$R_\tau(\beta, s) := \frac{1}{\tau} \{x, y(\tau)\}_G$$

converges weakly to zero. Namely, for all $f \in L^1(E, d\mu_H)$,

$$\lim_{\tau \rightarrow \infty} \int_E R_\tau(\beta, s) f(\beta, s) d\mu_H(\beta, s) = 0.$$

This weak convergence can be improved to strong convergence $\mu_H(E)$ -almost everywhere. Thus, the limiting modular symbol satisfies

$$\{ \{*, \beta\} \}_G \equiv 0 \quad \text{a.e. on } E.$$

This result depends upon the properties of the operator L_1 and the result on the T -invariant measure. In fact, to get the result on the weak convergence ([70]) one notices that the limit (2.29) computing limiting modular symbols can be evaluated in terms of a limit of iterates of the Perron–Frobenius operator, by

$$\lim_n \frac{1}{\lambda_0 n} \sum_{k=1}^n \int_{[0,1] \times \mathbb{P}} f(\varphi \circ T^k) = \lim_n \frac{1}{\lambda_0 n} \sum_{k=1}^n \int_{[0,1] \times \mathbb{P}} (L_1^k f) \varphi,$$

where $\lambda(\beta) = \lambda_0$ a.e. in $[0, 1]$.

By the convergence of $L_1^k 1$ to the density h of the T -invariant measure and of

$$L_1^k f \rightarrow \left(\int f d\mu \right) h,$$

this yields

$$\begin{aligned} \int_{[0,1] \times \mathbb{P}} \{ \{ *, \beta \} \} f(\beta, t) d\mu(\beta, t) &= \left(\int_{[0,1] \times \mathbb{P}} f d\mu \right) \left(\int_{[0,1] \times \mathbb{P}} \varphi h d\mu \right) \\ &= \left(\int f d\mu \right) \frac{1}{2\#\mathbb{P}} \sum_{s \in \mathbb{P}} \varphi(s). \end{aligned}$$

It is then easy to check that the sum $\sum_{s \in \mathbb{P}} \varphi(s) = 0$ since each term in the sum changes sign under the action of the inversion $\sigma \in \mathrm{PGL}(2, \mathbb{Z})$ with $\sigma^2 = 1$, but the sum is globally invariant under σ .

The argument extends to the case of other T -invariant subsets of $[0, 1] \times \mathbb{P}$ for which the corresponding Perron–Frobenius operator L_{E, δ_E} has analogous properties (*cf.* [71]). The weak convergence proved by this type of argument can be improved to strong convergence by applying the strong law of large numbers to the “random variables” $\varphi_k = \varphi \circ T^k$ (*cf.* [71] for details). The result effectively plays the role of an ergodic theorem for the shift T on E .

5. Hecke eigenforms

A very important question is what happens to modular forms at the noncommutative boundary of the modular curves. There is a variety of phenomena in the theory of modular forms that hint to the fact that a suitable class of “modular forms” survives on the noncommutative boundary. Zagier introduced the term “quantum modular forms” to denote this important and yet not sufficiently understood class of examples. Some aspects of modular forms “pushed” to the noncommutative boundary were analyzed in [70], in the form of certain averages involving modular symbols and Dirichlet series related to modular forms of weight 2. We recall here the main results in this case.

We shall now consider the case of congruence subgroups $G = \Gamma_0(p)$, for p a prime.

Let ω be a holomorphic differential (also called a differential of the first kind) on the modular curve $X_{\Gamma_0(p)} = \Gamma_0(p) \backslash \mathbb{H}$. Let $\Phi = \varphi^*(\omega)/dz$ be the pullback under the projection $\varphi : \mathbb{H} \rightarrow X_{\Gamma_0(p)}$.

Let Φ be an eigenfunction for all the Hecke operators

$$T_n = \sum_{d|n} \sum_{b=0}^{d-1} \begin{pmatrix} n/d & b \\ 0 & d \end{pmatrix}$$

with $(p, n) = 1$,

$$T_n \Phi = c_n \Phi.$$

Then the L-function of ω is given by

$$L_\omega(s) = -\frac{(2\pi)^s}{(2\pi i)\Gamma(s)} \int_0^\infty \Phi(iy) y^{s-1} dy$$

$$L_\omega(s) = \sum_{n=1}^{\infty} c_n n^{-s}.$$

There are many very interesting arithmetic properties of the integrals of such Hecke eigenforms on modular symbols (Manin [68]).

In particular, one has ([68]) the following relation between L_ω and modular symbols:

$$(2.37) \quad (\sigma(n) - c_n) L_\omega(1) = \sum_{d|n, b \bmod d} \int_{\{0, b/d\}} \omega,$$

with $\sigma(n) = \sum_{d|n} d$, from which one obtains

$$(2.38) \quad \sum_{q:(q,p)=1} q^{-(2+t)} \sum_{q' \leq q, (q,q')=1} \int_{\{0, q'/q\}} \omega$$

$$= \left[\frac{\zeta^{(p)}(1+t)}{\zeta^{(p)}(2+t)} - \frac{L_\omega^{(p)}(2+t)}{\zeta^{(p)}(2+t)^2} \right] \int_0^{i\infty} \phi^*(\omega)$$

Here $L_\omega^{(p)}$ is the Mellin transform of Φ with omitted Euler p -factor, and $\zeta(s)$ the Riemann zeta, with corresponding $\zeta^{(p)}$, that is, $L_\omega^{(p)}(s) = \sum_{n:(n,p)=1} c_n n^{-s}$ and $\zeta^{(p)}(s) = \sum_{n:(n,p)=1} n^{-s}$.

It is therefore interesting to study the properties of integrals on limiting modular symbols (*cf.* [70]) and extensions of (2.37) (2.38).

To this purpose, in [70] a suitable class of functions on the boundary $\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}$ (or just $[0, 1] \times \mathbb{P}$) was introduced.

These are functions of the form

$$(2.39) \quad \ell(f, \beta) = \sum_{k=1}^{\infty} f(q_k(\beta), q_{k-1}(\beta)).$$

Here f is a complex valued function defined on pairs of coprime integers (q, q') with $q \geq q' \geq 1$ and with $f(q, q') = O(q^{-\epsilon})$ for some $\epsilon > 0$, and $q_k(\beta)$ are the successive denominators of the continued fraction expansion of $\beta \in [0, 1]$.

The reason for this choice of functions is given by the following classical result of Lévy (1929).

PROPOSITION 5.1. *For a function f as above, we have*

$$(2.40) \quad \int_0^1 \ell(f, \alpha) d\alpha = \sum' \frac{f(q, q')}{q(q+q')}.$$

Sums and integrals here converge absolutely and uniformly.

We can interpret the summing over pairs of successive denominators as a property that replaces modularity, when “pushed to the boundary”.

Through this class of functions it is possible recast certain averages related to modular symbols on X_G , completely in terms of function theory on the “boundary” space $\Gamma \backslash (\mathbb{P}^1(\mathbb{R}) \times \mathbb{P})$. A typical result of this sort is the following ([70]).

Upon choosing

$$f(q, q') = \frac{q + q'}{q^{1+t}} \int_{\{0, q'/q\}_G} \omega,$$

one obtains

$$\int_0^1 \ell(f, \beta) d\mu_{Leb}(\beta) = \left[\frac{\zeta(1+t)}{\zeta(2+t)} - \frac{L_\omega^{(p)}(2+t)}{\zeta^{(p)}(2+t)^2} \right] \int_0^{i\infty} \phi^*(\omega),$$

which expresses the Mellin transform of a Hecke eigenform in terms of a boundary average.

Analogous results exist for different choices of $f(q, q')$, for Eisenstein series twisted by modular symbols, double logarithms at roots of unity, etc.

In fact, this result also shows that, even when the limiting modular symbol vanishes, one can still associate nontrivial homology classes to the geodesics with irrational ends.

In fact, for the case of $G = \Gamma_0(p)$ let us consider

$$(2.41) \quad C(f, \beta) := \sum_{n=1}^{\infty} \frac{q_{n+1}(\beta) + q_n(\beta)}{q_{n+1}(\beta)^{1+t}} \left\{ 0, \frac{q_n(\beta)}{q_{n+1}(\beta)} \right\}_{\Gamma_0(p)}.$$

This defines, for $\Re(t) > 0$ and for almost all β , a homology class in $H_1(X_G, \text{cusps}, \mathbb{R})$ such that the integral average

$$\ell(f, \beta) = \int_{C(f, \beta)} \omega$$

on $[0, 1]$ recovers Mellin transforms of cusp forms by

$$\int_0^1 \int_{C(f, \beta)} \omega d\mu_{Leb}(\beta) = \left[\frac{\zeta(1+t)}{\zeta(2+t)} - \frac{L_\omega^{(p)}(2+t)}{\zeta^{(p)}(2+t)^2} \right] \int_0^{i\infty} \phi^*(\omega).$$

An estimate

$$\frac{q_{n+1}(\beta) + q_n(\beta)}{q_{n+1}(\beta)^{1+t}} \left\{ 0, \frac{q_n(\beta)}{q_{n+1}(\beta)} \right\}_G \sim e^{-(5+2t)n\lambda(\beta)} \sum_{k=1}^n \varphi \circ T^k(s)$$

shows that the series involved are absolutely convergent.

6. Selberg zeta function

Infinite geodesics on X_G are the image image of infinite geodesics on $\mathbb{H}^2 \times \mathbb{P}$ with ends on $\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}$. Thus, they can be coded by (ω^-, ω^+, s) , with $(\omega^\pm, s) = \text{endpoints in } \mathbb{P}^1(\mathbb{R}) \times \{s\}$, $s \in \mathbb{P}$, $\omega^- \in (-\infty, -1]$, $\omega^+ \in [0, 1]$.

If ω^\pm are not cusp points, then we have infinite continued fraction expansions of these endpoints,

$$\begin{aligned}\omega^+ &= [k_0, k_1, \dots, k_r, k_{r+1}, \dots] \\ \omega^- &= [k_{-1}; k_{-2}, \dots, k_{-n}, k_{-n-1}, \dots],\end{aligned}$$

hence the corresponding geodesics are coded by (ω, s) , $s \in \mathbb{P}$, where ω is a doubly infinite sequence

$$\omega = \dots k_{-(n+1)} k_{-n} \dots k_{-1} k_0 k_1 \dots k_n \dots$$

The equivalence relation of passing to the quotient by the group action is implemented by the invertible (double sided) shift:

$$T(\omega^+, \omega^-, s) = \left(\frac{1}{\omega^+} - \left[\frac{1}{\omega^+} \right], \frac{1}{\omega^- - [1/\omega^+]}, \begin{pmatrix} -[1/\omega^+] & 1 \\ 1 & 0 \end{pmatrix} \cdot s \right).$$

In particular, the closed geodesics in X_G correspond to the case where the endpoints ω^\pm are the attractive and repelling fixed points of a hyperbolic element in the group. This corresponds to the case where (ω, s) is a periodic point for the shift T .

The Selberg zeta function is a suitable “generating function” for the closed geodesics in X_G . It is given by

$$Z_G(s) = \prod_{m=0}^{\infty} \prod_{\gamma} (1 - e^{-(s+m)\ell(\gamma)}),$$

where γ is a primitive closed geodesic of length $\ell(\gamma)$.

This can also be expressed in terms of the generalized Gauss shift by the following ([13], [70])

THEOREM 6.1. *The Selberg zeta function for $G \subset \text{PGL}(2, \mathbb{Z})$ of finite index is computed by the Fredholm determinant of the Ruelle transfer operator (2.31),*

$$Z_G(s) = \det(1 - L_s).$$

An analogous result holds for finite index subgroups of $\text{SL}(2, \mathbb{Z})$, where one gets $\det(1 - L_s^2)$. There are also generalizations to other T -invariant sets E , where $\det(1 - L_{E,s})$ corresponds to a suitable “Selberg zeta” that only counts certain classes of closed geodesics.

FIGURE 8. The modular complex and the tree of $\mathrm{PSL}(2, \mathbb{Z})$

7. The modular complex and K -theory of C^* -algebras

When we interpret the “boundary” $\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}$ with the action of Γ as the noncommutative space C^* -algebra $C(\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}) \rtimes \Gamma$, it is possible to reinterpret some of the arithmetic properties of modular curves in terms of these operator algebras. For instance, the modular symbols determine certain elements in the K -theory of this C^* -algebra, and the modular complex and the exact sequence of relative homology (2.11) can be identified canonically with the Pimsner six terms exact sequence for K -theory of this C^* -algebra.

For $\Gamma = \mathrm{PSL}(2, \mathbb{Z})$ and $G \subset \Gamma$ a finite index subgroup, we use the notation $X := \mathbb{P}^1(\mathbb{R}) \times \mathbb{P}$, and $\Gamma_\sigma := \langle \sigma \rangle = \mathbb{Z}/2$ and $\Gamma_\tau := \langle \tau \rangle = \mathbb{Z}/3$.

The group Γ acts on the tree with edges $T^1 \simeq \Gamma$ and vertices $T^0 \simeq \Gamma/\langle \sigma \rangle \cup \Gamma/\langle \tau \rangle$. This tree is embedded in \mathbb{H}^2 with vertices at the elliptic points and geodesic edges, as the dual graph of the triangulation (Figure 3) of the modular complex (Figure 8).

For a group acting on a tree there is a Pimsner six terms exact sequence, computing the K -theory of the crossed product C^* -algebra (for $\mathcal{A} = C(X)$)

$$\begin{array}{ccccc}
 K_0(\mathcal{A}) & \xrightarrow{\alpha} & K_0(\mathcal{A} \rtimes \Gamma_\sigma) \oplus K_0(\mathcal{A} \rtimes \Gamma_\tau) & \xrightarrow{\tilde{\alpha}} & K_0(\mathcal{A} \rtimes \Gamma) \\
 \uparrow & & & & \downarrow \\
 K_1(\mathcal{A} \rtimes \Gamma) & \xleftarrow{\tilde{\beta}} & K_1(\mathcal{A} \rtimes \Gamma_\sigma) \oplus K_1(\mathcal{A} \rtimes \Gamma_\tau) & \xleftarrow{\beta} & K_1(\mathcal{A})
 \end{array}$$

A direct inspection of the maps in this exact sequence shows that it contains a subsequence, which is canonically isomorphic to the algebraic presentation of the modular complex, compatibly with the covering maps between modular curves for different congruence subgroups.

THEOREM 7.1. *The algebraic presentation of the modular complex*

$$0 \rightarrow H_{cusps} \rightarrow \mathbb{Z}[\mathbb{P}] \rightarrow \mathbb{Z}[\mathbb{P}_R] \oplus \mathbb{Z}[\mathbb{P}_I] \rightarrow \mathbb{Z} \rightarrow 0$$

is canonically isomorphic to the sequence

$$0 \rightarrow Ker(\beta) \rightarrow \mathbb{Z}[\mathbb{P}] \rightarrow \mathbb{Z}[\mathbb{P}_I] \oplus \mathbb{Z}[\mathbb{P}_R] \rightarrow Im(\tilde{\beta}) \rightarrow 0.$$

A more geometric explanation for this exact sequence is the following. The Lie group $PSL(2, \mathbb{R})$ can be identified with the circle bundle (unit sphere bundle) over the hyperbolic plane $\mathbb{H} = PSL(2, \mathbb{R})/PSO(2)$. Thus, the unit tangent bundle to the modular curve X_G is given by the quotient $T_1X_G = G \backslash PSL(2, \mathbb{R})$.

On the other hand, we can identify $\mathbb{P}^1(\mathbb{R}) = B \backslash PSL(2, \mathbb{R})$, the quotient by the upper triangular matrices B , so that we have Morita equivalent algebras

$$C(\mathbb{P}^1(\mathbb{R})) \rtimes G \simeq C(T_1X_G) \rtimes B.$$

The right hand side is the semidirect product of two \mathbb{R} -actions. Thus, by the Thom isomorphism [16] we have

$$K_*(C(T_1X_G) \rtimes B) \cong K_*(C(T_1X_G))$$

where $K^*(T_1X_G)$ is related to $K^*(X_G)$ by the Gysin exact sequence.

A construction of crucial importance in noncommutative geometry is the classifying space for proper actions $\underline{B}G$ of Baum–Connes [6], the homotopy quotient $X \times_G \underline{E}G$ and the μ -map

$$\mu : K^*(X \times_G \underline{E}G) \rightarrow K_*(C(X) \rtimes G)$$

relating the topologically defined K -theory to the analytic K -theory of C^* -algebras.

In a sense, for noncommutative spaces that are obtained as quotients by “bad” equivalence relations, the homotopy quotient is a “commutative shadow” from which much crucial information on the topology can be read (*cf.* [6], [18]).

In our case we have $\underline{E}G = \mathbb{H}^2$ and the μ -map is an isomorphism (the Baum–Connes conjecture holds). By retracting $\underline{E}G = \mathbb{H}^2$ to the tree of $PSL(2, \mathbb{Z})$ and applying the Mayer–Vietoris sequence to vertices and edges one obtains the Pimsner six terms exact sequence.

8. Intermezzo: Chaotic Cosmology

We digress momentarily on a topic from General Relativity, which turns out to be closely related to the “noncommutative compactification” of the modular curve X_G with G the congruence subgroup $\Gamma_0(2)$ ([70]).

An important problem in cosmology is understanding how anisotropy in the early universe affects the long time evolution of space-time. This problem is relevant to the study of the beginning of galaxy formation and in relating the anisotropy of the background radiation to the appearance of the universe today.

We follow [5] for a brief summary of anisotropic and chaotic cosmology. The simplest significant cosmological model that presents strong anisotropic properties is given by the Kasner metric

$$(2.42) \quad ds^2 = -dt^2 + t^{2p_1} dx^2 + t^{2p_2} dy^2 + t^{2p_3} dz^2,$$

where the exponents p_i are constants satisfying $\sum p_i = 1 = \sum_i p_i^2$. Notice that, for $p_i = d \log g_{ii} / d \log g$, the first constraint $\sum_i p_i = 1$ is just the condition that $\log g_{ij} = 2\alpha \delta_{ij} + \beta_{ij}$ for a traceless β , while the second constraint $\sum_i p_i^2 = 1$ amounts to the condition that, in the Einstein equations written in terms of α and β_{ij} ,

$$\begin{aligned} \left(\frac{d\alpha}{dt} \right)^2 &= \frac{8\pi}{3} \left(T^{00} + \frac{1}{16\pi} \left(\frac{d\beta_{ij}}{dt} \right)^2 \right) \\ e^{-3\alpha} \frac{d}{dt} \left(e^{3\alpha} \frac{d\beta_{ij}}{dt} \right) &= 8\pi \left(T_{ij} - \frac{1}{3} \delta_{ij} T_{kk} \right), \end{aligned}$$

the term T^{00} is negligible with respect to the term $(d\beta_{ij}/dt)^2/16\pi$, which is the ‘‘effective energy density’’ of the anisotropic motion of empty space, contributing together with a matter term to the Hubble constant.

Around 1970, Belinsky, Khalatnikov, and Lifshitz introduced a cosmological model (*mixmaster universe*) where they allowed the exponents p_i of the Kasner metric to depend on a parameter u ,

$$(2.43) \quad \begin{aligned} p_1 &= \frac{-u}{1+u+u^2} \\ p_2 &= \frac{1+u}{1+u+u^2} \\ p_3 &= \frac{u(1+u)}{1+u+u^2} \end{aligned}$$

Since for fixed u the model is given by a Kasner space-time, the behavior of this universe can be approximated for certain large intervals of time by a Kasner metric. In fact, the evolution is divided into Kasner eras and each era into cycles. During each era the mixmaster universe goes through a volume compression. Instead of resulting in a collapse, as with the Kasner metric, high negative curvature develops resulting in a bounce (transition to a new era) which starts again a behavior approximated by a Kasner metric, but with a different value of the parameter u . Within each era, most of the volume compression is due

to the scale factors along one of the space axes, while the other scale factors alternate between phases of contraction and expansion. These alternating phases separate cycles within each era.

More precisely, we are considering a metric

$$(2.44) \quad ds^2 = -dt^2 + a(t)dx^2 + b(t)dy^2 + c(t)dz^2,$$

generalizing the Kasner metric (2.42). We still require that (2.44) admits $SO(3)$ symmetry on the space-like hypersurfaces, and that it presents a singularity at $t \rightarrow 0$. In terms of logarithmic time $d\Omega = -\frac{dt}{abc}$, the *mixmaster universe* model of Belinsky, Khalatnikov, and Lifshitz admits a discretization with the following properties:

1. The time evolution is divided in Kasner eras $[\Omega_n, \Omega_{n+1}]$, for $n \in \mathbb{Z}$. At the beginning of each era we have a corresponding discrete value of the parameter $u_n > 1$ in (2.43).
2. Each era, where the parameter u decreases with growing Ω , can be subdivided in cycles corresponding to the discrete steps $u_n, u_n - 1, u_n - 2$, etc. A change $u \rightarrow u - 1$ corresponds, after acting with the permutation (12)(3) on the space coordinates, to changing u to $-u$, hence replacing contraction with expansion and conversely. Within each cycle the space-time metric is approximated by the Kasner metric (2.42) with the exponents p_i in (2.43) with a fixed value of $u = u_n - k > 1$.
3. An era ends when, after a number of cycles, the parameter u_n falls in the range $0 < u_n < 1$. Then the bouncing is given by the transition $u \rightarrow 1/u$ which starts a new series of cycles with new Kasner parameters and a permutation (1)(23) of the space axis, in order to have again $p_1 < p_2 < p_3$ as in (2.43).

Thus, the transition formula relating the values u_n and u_{n+1} of two successive Kasner eras is

$$u_{n+1} = \frac{1}{u_n - [u_n]},$$

which is exactly the shift of the continued fraction expansion, $Tx = 1/x - [1/x]$, with $x_{n+1} = Tx_n$ and $u_n = 1/x_n$.

The previous observation is the key to a geometric description of solutions of the mixmaster universe in terms of geodesics on a modular curve (*cf.* [70]).

THEOREM 8.1. *Consider the modular curve $X_{\Gamma_0(2)}$. Each infinite geodesic γ on $X_{\Gamma_0(2)}$ not ending at cusps determines a mixmaster universe.*

In fact, an infinite geodesic on $X_{\Gamma_0(2)}$ is the image under the quotient map

$$\pi_\Gamma : \mathbb{H}^2 \times \mathbb{P} \rightarrow \Gamma \backslash (\mathbb{H}^2 \times \mathbb{P}) \cong X_G,$$

where $\Gamma = \mathrm{PGL}(2, \mathbb{Z})$, $G = \Gamma_0(2)$, and $\mathbb{P} = \Gamma/G \cong \mathbb{P}^1(\mathbb{F}_2) = \{0, 1, \infty\}$, of an infinite geodesic on $\mathbb{H}^2 \times \mathbb{P}$ with ends on $\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}$. We consider the elements of $\mathbb{P}^1(\mathbb{F}_2)$ as labels assigned to the three space axes, according to the identification

$$(2.45) \quad \begin{aligned} 0 &= [0 : 1] && \mapsto z \\ \infty &= [1 : 0] && \mapsto y \\ 1 &= [1 : 1] && \mapsto x. \end{aligned}$$

As we have seen, geodesics can be coded in terms of data (ω^-, ω^+, s) with the action of the shift T .

The data (ω, s) determine a mixmaster universe, with the $k_n = [u_n] = [1/x_n]$ in the Kasner eras, and with the transition between subsequent Kasner eras given by $x_{n+1} = Tx_n \in [0, 1]$ and by the permutation of axes induced by the transformation

$$\begin{pmatrix} -k_n & 1 \\ 1 & 0 \end{pmatrix}$$

acting on $\mathbb{P}^1(\mathbb{F}_2)$. It is easy to verify that, in fact, this acts as the permutation $0 \mapsto \infty$, $1 \mapsto 1$, $\infty \mapsto 0$, if k_n is even, and $0 \mapsto \infty$, $1 \mapsto 0$, $\infty \mapsto 1$ if k_n is odd, that is, after the identification (2.45), as the permutation (1)(23) of the space axes (x, y, z) , if k_n is even, or as the product of the permutations (12)(3) and (1)(23) if k_n is odd. This is precisely what is obtained in the mixmaster universe model by the repeated series of cycles within a Kasner era followed by the transition to the next era.

Data (ω, s) and $T^m(\omega, s)$, $m \in \mathbb{Z}$, determine the same solution up to a different choice of the initial time.

There is an additional time-symmetry in this model of the evolution of mixmaster universes (*cf.* [5]). In fact, there is an additional parameter δ_n in the system, which measures the initial amplitude of each cycle. It is shown in [5] that this is governed by the evolution of a parameter

$$v_n = \frac{\delta_{n+1}(1 + u_n)}{1 - \delta_{n+1}}$$

which is subject to the transformation across cycles $v_{n+1} = [u_n] + v_n^{-1}$. By setting $y_n = v_n^{-1}$ we obtain

$$y_{n+1} = \frac{1}{(y_n + [1/x_n])},$$

hence we see that we can interpret the evolution determined by the data (ω^+, ω^-, s) with the shift T either as giving the complete evolution of the u -parameter towards and away from the cosmological singularity, or as giving the simultaneous evolution of the two parameters (u, v) while approaching the cosmological singularity.

This in turn determines the complete evolution of the parameters (u, δ, Ω) , where Ω_n is the starting time of each cycle. For the explicit recursion $\Omega_{n+1} = \Omega_{n+1}(\Omega_n, x_n, y_n)$ see [5].

The result of Theorem 4.5 on the unique T -invariant measure on $[0, 1] \times \mathbb{P}$

$$(2.46) \quad d\mu(x, s) = \frac{\delta(s) dx}{3 \log(2) (1+x)},$$

implies that the alternation of the space axes is uniform over the time evolution, namely the three axes provide the scale factor responsible for volume compression with equal frequencies.

The Perron-Frobenius operator for the shift (2.24) yields the density of the invariant measure (2.46) satisfying $L_1 f = f$. The top eigenvalue η_σ of L_σ is related to the topological pressure by $\eta_\sigma = \exp(P(\sigma))$. This can be estimated numerically, using the technique of [4] and the integral kernel operator representation of §1.3 of [70].

The interpretation of solutions in terms of geodesics provides a natural way to single out and study certain special classes of solutions on the basis of their geometric properties. Physically, such special classes of solutions exhibit different behaviors approaching the cosmological singularity.

For instance, the data (ω^+, s) corresponding to an eventually periodic sequence $k_0 k_1 \dots k_m \dots$ of some period $\overline{a_0 \dots a_\ell}$ correspond to those geodesics on $X_{\Gamma_0(2)}$ that asymptotically wind around the closed geodesic identified with the doubly infinite sequence $\dots a_0 \dots a_\ell a_0 \dots a_\ell \dots$. Physically, these universes exhibit a pattern of cycles that recurs periodically after a finite number of Kasner eras.

Another special class of solutions is given by the Hensley Cantor sets (*cf.* [72]). These are the mixmaster universes for which there is a fixed upper bound N to the number of cycles in each Kasner era.

In terms of the continued fraction description, these solutions correspond to data (ω^+, s) with ω^+ in the Hensley Cantor set $E_N \subset [0, 1]$. The set E_N is given by all points in $[0, 1]$ with all digits in the continued fraction expansion bounded by N (*cf.* [51]). In more geometric terms, these correspond to geodesics on the modular curve $X_{\Gamma_0(2)}$ that wander only a finite distance into a cusp.

On the set E_N the Ruelle and Perron–Frobenius operators are given by

$$(2.47) \quad (L_{\sigma,N}f)(x, s) = \sum_{k=1}^N \frac{1}{(x+k)^{2\sigma}} f\left(\frac{1}{x+k}, \begin{pmatrix} 0 & 1 \\ 1 & k \end{pmatrix} \cdot s\right).$$

This operator still has a unique invariant measure μ_N , whose density satisfies $\mathcal{L}_{2 \dim_H(E_N), N} f = f$, with

$$\dim_H(E_N) = 1 - \frac{6}{\pi^2 N} - \frac{72 \log N}{\pi^4 N^2} + O(1/N^2)$$

the Hausdorff dimension of the Cantor set E_N . Moreover, the top eigenvalue η_σ of $\mathcal{L}_{\sigma,N}$ is related to the Lyapunov exponent by

$$\lambda(x) = \frac{d}{d\sigma} \eta_\sigma \Big|_{\sigma=\dim_H(E_N)},$$

for μ_N -almost all $x \in E_N$.

A consequence of this characterization of the time evolution in terms of the dynamical system (2.24) is that we can study global properties of suitable *moduli spaces* of mixmaster universes. For instance, the moduli space for time evolutions of the u -parameter approaching the cosmological singularity as $\Omega \rightarrow \infty$ is given by the quotient of $[0, 1] \times \mathbb{P}$ by the action of the shift T .

Similarly when we restrict to special classes of solutions, *e.g.* we can consider the “moduli space” $E_N \times \mathbb{P}$ modulo the action of T . In this example, the dynamical system T acting on $E_N \times \mathbb{P}$ is a *subshift of finite type*, and the resulting noncommutative space is a Cuntz–Krieger algebra [42]. This is an interesting class of C^* -algebras, generated by partial isometries. Another such algebra will play a fundamental role in the geometry at arithmetic infinity, which is the topic of the next lecture.

In the example of the mixmaster dynamics on the Hensley Cantor sets, the shift T is described by the Markov partition

$$\mathcal{A}_N = \{((k, t), (\ell, s)) \mid U_{k,t} \subset T(U_{\ell,s})\},$$

for $k, \ell \in \{1, \dots, N\}$, and $s, t \in \mathbb{P}$, with sets $U_{k,t} = U_k \times \{t\}$, where $U_k \subset E_N$ are the clopen subsets where the local inverses of T are defined,

$$U_k = \left[\frac{1}{k+1}, \frac{1}{k} \right] \cap E_N.$$

This Markov partition determines a matrix A_N , with entries $(A_N)_{kt, \ell s} = 1$ if $U_{k,t} \subset T(U_{\ell,s})$ and zero otherwise (*cf.* Figure 9).

FIGURE 9. The directed graph of the matrix A_2

PROPOSITION 8.2. *The 3×3 submatrices $A_{kl} = (A_{(k,t),(\ell,s)})_{s,t \in \mathbb{P}}$ of the matrix A_N are of the form*

$$A_{k\ell} = \begin{cases} \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} & \ell = 2m \\ \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} & \ell = 2m + 1 \end{cases}$$

This is just the condition $U_{k,t} \subset T(U_{\ell,s})$ written as

$$\begin{pmatrix} 0 & 1 \\ 1 & \ell \end{pmatrix} \cdot s = t,$$

together with the fact that the transformation

$$\begin{pmatrix} 0 & 1 \\ 1 & \ell \end{pmatrix}$$

acts on $\mathbb{P}^1(\mathbb{F}_2)$ as the permutation $0 \mapsto \infty$, $1 \mapsto 1$, $\infty \mapsto 0$, when ℓ is even, and $\infty \mapsto 0$, $0 \mapsto 1$, $1 \mapsto \infty$ if ℓ is odd.

As a non-commutative space associated to the Markov partition we consider the Cuntz–Krieger C^* -algebra \mathcal{O}_{A_N} (cf. [42]), which is the universal C^* -algebra generated by partial isometries S_{kt} satisfying the relations

$$\sum_{(k,t)} S_{kt} S_{kt}^* = 1,$$

$$S_{\ell s}^* S_{\ell s} = \sum_{(k,t)} A_{(k,t),(\ell,s)} S_{kt} S_{kt}^*.$$

Topological invariants of this C^* -algebra reflect dynamical properties of the shift T .

CHAPTER 3

Quantum statistical mechanics and Galois theory

This chapter is dedicated to a brief review of the joint work of Alain Connes and the author on quantum statistical mechanics of \mathbb{Q} -lattices [29], [30]. It also includes a discussion of the relation to the explicit class field theory problem for imaginary quadratic fields, following joint work of Alain Connes, Niranjana Ramachandran, and the author [31], as well as a brief review of some of Manin's idea on real quadratic fields and noncommutative tori with real multiplication [63].

The main notion that we consider in this chapter is that of commensurability classes of \mathbb{Q} -lattices, according to the following definition.

DEFINITION 0.1. *A \mathbb{Q} -lattice in \mathbb{R}^n consists of a pair (Λ, ϕ) of a lattice $\Lambda \subset \mathbb{R}^n$ (a cocompact free abelian subgroup of \mathbb{R}^n of rank n) together with a system of labels of its torsion points given by a homomorphism of abelian groups*

$$\phi : \mathbb{Q}^n / \mathbb{Z}^n \longrightarrow \mathbb{Q}\Lambda / \Lambda.$$

A \mathbb{Q} -lattice is invertible if ϕ is an isomorphism.

Two \mathbb{Q} -lattices are commensurable,

$$(\Lambda_1, \phi_1) \sim (\Lambda_2, \phi_2),$$

iff $\mathbb{Q}\Lambda_1 = \mathbb{Q}\Lambda_2$ and

$$\phi_1 = \phi_2 \pmod{\Lambda_1 + \Lambda_2}$$

One can check that, indeed, commensurability defines an equivalence relation among \mathbb{Q} -lattices. The interesting aspect of this equivalence relation is that the quotient provides another typical case which is best described through noncommutative geometry. For this it is crucial that we consider non-invertible \mathbb{Q} -lattices. In fact, most \mathbb{Q} -lattices are not commensurable to an invertible one, while two invertible \mathbb{Q} -lattices are commensurable if and only if they are equal.

In the following, we denote by \mathcal{L}_n the set of commensurability classes of \mathbb{Q} -lattices in \mathbb{R}^n . The topology on this space is encoded in a noncommutative algebra of coordinates, namely a C^* -algebra $C^*(\mathcal{L}_n)$. We will discuss in some detail only the cases $n = 1$ (Bost–Connes system) and $n = 2$ (the case considered in [29]). In these cases, we will

FIGURE 1. Generic and invertible 2-dimensional \mathbb{Q} -lattices

look at commensurability classes of \mathbb{Q} -lattices up to scaling, namely the quotients $\mathcal{L}_1/\mathbb{R}_+^*$ and $\mathcal{L}_2/\mathbb{C}^*$. The corresponding C^* -algebras

$$C^*(\mathcal{L}_1/\mathbb{R}_+^*) \quad \text{and} \quad C^*(\mathcal{L}_2/\mathbb{C}^*)$$

are endowed with a natural time evolution (a 1-parameter family of automorphisms). Thus, one can consider them as quantum statistical mechanical systems and look for equilibrium states, depending on a thermodynamic parameter β (inverse temperature). The interesting connection to arithmetic arises from the fact that the action of symmetries of the system on equilibrium states at zero temperature can be described in terms of Galois theory. In the 1-dimensional case of Bost–Connes, this will happen via the class field theory of \mathbb{Q} , namely the Galois theory of the cyclotomic field \mathbb{Q}^{cycl} . In the two dimensional case, the picture is more elaborate and involves the automorphisms of the field of modular functions.

1. Quantum Statistical Mechanics

In classical statistical mechanics a state is a probability measure μ on the phase space that assigns to each observable f an expectation value, in the form of an average

$$(3.1) \quad \int f d\mu.$$

In particular, for a Hamiltonian system, the macroscopic thermodynamic behavior is described via the Gibbs canonical ensemble. This is the measure

$$(3.2) \quad d\mu_G = \frac{1}{Z} e^{-\beta H} d\mu_{Liouville},$$

normalized by $Z = \int e^{-\beta H} d\mu_{Liouville}$, with a thermodynamic parameter $\beta = (kT)^{-1}$, for T the temperature and k the Boltzmann constant (which we can set equal to one in suitable units).

A quantum statistical mechanical system consists of the data of an algebra of observables (a C^* -algebra \mathcal{A}), together with a time evolution given as a 1-parameter family of automorphisms $\sigma_t \in \text{Aut}(\mathcal{A})$. We refer to the pair (\mathcal{A}, σ_t) as a C^* -dynamical system. These data describe the microscopic quantum mechanical evolution of the system.

The macroscopic thermodynamical properties are encoded in the equilibrium states of the system, depending on the inverse temperature β . While the Gibbs measure in the classical case is defined in terms of the Hamiltonian and the symplectic structure on the phase space, the notion of equilibrium state in the quantum statistical mechanical setting only depends on the algebra of observables and its time evolution, and does not involve any additional structure like the symplectic structure or the approximation by regions of finite volume.

We first need to recall the notion of states. These can be thought of as probability measures on noncommutative spaces.

DEFINITION 1.1. *Given a unital C^* -algebra \mathcal{A} , a state on \mathcal{A} is a linear functional $\varphi : \mathcal{A} \rightarrow \mathbb{C}$ satisfying normalization and positivity,*

$$(3.3) \quad \varphi(1) = 1, \quad \varphi(a^*a) \geq 0.$$

When the C^ -algebra \mathcal{A} is non unital, the condition $\varphi(1) = 1$ is replaced by $\|\varphi\| = 1$ where*

$$(3.4) \quad \|\varphi\| := \sup_{x \in \mathcal{A}, \|x\| \leq 1} |\varphi(x)|.$$

Such states are restrictions of states on the unital C^ -algebra $\tilde{\mathcal{A}}$ obtained by adjoining a unit.*

Before giving the general definition of equilibrium states via the KMS condition, we can see equilibrium states in the simple case of a system with finitely many quantum degrees of freedom. In this case, the algebra of observables is the algebra of operators in a Hilbert space \mathcal{H} and the time evolution is given by $\sigma_t(a) = e^{itH} a e^{-itH}$, where H is a positive self-adjoint operator such that $\exp(-\beta H)$ is trace class for

FIGURE 2. The KMS condition

any $\beta > 0$. For such a system, the analog of (3.2) is

$$(3.5) \quad \varphi(a) = \frac{1}{Z} \operatorname{Tr} (a e^{-\beta H}) \quad \forall a \in A,$$

with the normalization factor $Z = \operatorname{Tr}(\exp(-\beta H))$.

The Kubo–Martin–Schwinger condition (KMS) (*cf.* [11], [47], [48]) describing equilibrium states of more general quantum statistical mechanical systems generalizes (3.5) beyond the range of temperatures where $\exp(-\beta H)$ is trace class.

DEFINITION 1.2. *Given a C^* -dynamical system (\mathcal{A}, σ_t) , a state φ on \mathcal{A} satisfies the KMS condition at inverse temperature $0 < \beta < \infty$ iff, for all $a, b \in \mathcal{A}$, there exists a function $F_{a,b}(z)$ holomorphic on the strip $0 < \Im(z) < \beta$ continuous to the boundary and bounded, such that for all $t \in \mathbb{R}$*

$$(3.6) \quad F_{a,b}(t) = \varphi(a\sigma_t(b)) \quad \text{and} \quad F_{a,b}(t + i\beta) = \varphi(\sigma_t(b)a).$$

KMS_∞ states are weak limits of KMS_β states as $\beta \rightarrow \infty$,

$$(3.7) \quad \varphi_\infty(a) = \lim_{\beta \rightarrow \infty} \varphi_\beta(a) \quad \forall a \in \mathcal{A}.$$

Our definition of KMS_∞ state is stronger than the one often adopted in the literature, which simply uses the existence, for each $a, b \in \mathcal{A}$, of a bounded holomorphic function $F_{a,b}(z)$ on the upper half plane such that $F_{a,b}(t) = \varphi(a\sigma_t(b))$. It is easy to see that this notions, which we

simply call the *ground states* of the system, is in fact weaker than the notion of KMS_∞ states given in Definition 1.2. For example, in the simplest case of the trivial time evolution, all states are ground states, while only tracial states are KMS_∞ states. Another advantage of our definition is that for all $0 < \beta \leq \infty$, the KMS_β states form a Choquet simplex and we can therefore consider the set \mathcal{E}_β of its extremal points. These give a good notion of *points* for the underlying noncommutative space. This will be especially useful in connection to an arithmetic structure specified by an arithmetic subalgebra $\mathcal{A}_\mathbb{Q}$ of \mathcal{A} on which one evaluates the KMS_∞ states. This will play a key role in the relation between the symmetries of the system and the action of the Galois group on states $\varphi \in \mathcal{E}_\infty$ evaluated on $\mathcal{A}_\mathbb{Q}$.

1.1. Symmetries. An important role in quantum statistical mechanics is played by symmetries. Typically, symmetries of the algebra \mathcal{A} compatible with the time evolution induce symmetries of the equilibrium states \mathcal{E}_β at different temperatures. Especially important are the phenomena of *symmetry breaking*. In such cases, there is a global underlying group G of symmetries of the algebra \mathcal{A} , but in certain ranges of temperature the choice of an equilibrium state φ breaks the symmetry to a smaller subgroup $G_\varphi = \{g \in G : g^*\varphi = \varphi\}$, where g^* denotes the induced action on states. Various systems can exhibit one or more phase transitions, or none at all. A typical situation in physical systems sees a unique KMS state for all values of the parameter above a certain critical temperature ($\beta < \beta_c$). This corresponds to a chaotic phase such as randomly distributed spins in a ferromagnet. When the system cools down and reaches the critical temperature, the unique equilibrium state branches off into a larger set KMS_β and the symmetry is broken by the choice of an extremal state in \mathcal{E}_β .

We will see that the case of $\mathcal{L}_1/\mathbb{R}_+^*$ gives rise to a system with a single phase transition ([8]), while in the case of $\mathcal{L}_2/\mathbb{C}^*$ the system has multiple phase transitions.

A very important point is that we need to consider both symmetries by automorphisms and by endomorphisms.

Automorphisms: A subgroup $G \subset \text{Aut}(\mathcal{A})$ is compatible with σ_t if for all $g \in G$ and for all $t \in \mathbb{R}$ we have $g\sigma_t = \sigma_t g$. There is then an induced action of G on KMS states and in particular on the set \mathcal{E}_β . If u is a unitary, acting on \mathcal{A} by

$$\text{Adu} : a \mapsto uau^*$$

and satisfying $\sigma_t(u) = u$, then we say that Adu is an inner automorphism of (\mathcal{A}, σ_t) . Inner automorphisms act trivially on KMS states.

Endomorphisms: Let $\rho\sigma_t = \sigma_t\rho$ be a $*$ -homomorphism. Consider the idempotent $e = \rho(1)$. If $\varphi \in \mathcal{E}_\beta$ is a state such that $\varphi(e) \neq 0$, then there is a well defined pullback $\rho^*\varphi$,

$$(3.8) \quad \rho^*(\varphi) = \frac{1}{\varphi(e)} \varphi \circ \rho.$$

Let u be an isometry compatible with the time evolution by

$$(3.9) \quad \sigma_t(u) = \lambda^{it} u \quad \lambda > 0.$$

One has $u^*u = 1$ and $uu^* = e$. We say that Adu defined by $a \mapsto uau^*$ is an inner endomorphism of (\mathcal{A}, σ_t) . The condition (3.9) ensures that $(\text{Adu})^*\varphi$ is well defined according to (3.8) and the KMS condition shows that the induced action of an inner endomorphism on KMS states is trivial.

One needs to be especially careful in defining the action of endomorphisms by (3.8). In fact, there are cases where for KMS_∞ states one finds only $\varphi(e) = 0$, yet it is still possible to define an interesting action of endomorphisms by a procedure of “warming up and cooling down”. For this to work one needs sufficiently favorable conditions, namely that the “warming up” map

$$(3.10) \quad W_\beta(\varphi)(a) = \frac{\text{Tr}(\pi_\varphi(a) e^{-\beta H})}{\text{Tr}(e^{-\beta H})}$$

gives a homeomorphism $W_\beta : \mathcal{E}_\infty \rightarrow \mathcal{E}_\beta$ for all β sufficiently large. One can then define the action by

$$(3.11) \quad (\rho^*\varphi)(a) = \lim_{\beta \rightarrow \infty} (\rho^*W_\beta(\varphi))(a),$$

for all $\varphi \in \mathcal{E}_\infty$ and all $a \in \mathcal{A}$.

2. The Bost–Connes system

We give the following geometric point of view on the BC system, following [31].

We use the notation $Sh(G, X) := G(\mathbb{Q}) \backslash (G(\mathbb{A}_f) \times X)$ for Shimura varieties (cf. [78]). Here $\mathbb{A}_f = \hat{\mathbb{Z}} \otimes \mathbb{Q}$ denotes the finite adèles of \mathbb{Q} , with $\hat{\mathbb{Z}} = \varprojlim_n \mathbb{Z}/n\mathbb{Z}$. The simplest case is for $G = \text{GL}_1$, where we consider

$$(3.12) \quad Sh(\text{GL}_1, \{\pm 1\}) = \text{GL}_1(\mathbb{Q}) \backslash (\text{GL}_1(\mathbb{A}_f) \times \{\pm 1\}) = \mathbb{Q}_+^* \backslash \mathbb{A}_f^*.$$

LEMMA 2.1. *The quotient (3.12) parameterizes the invertible 1-dimensional \mathbb{Q} -lattices up to scaling.*

In fact, first notice that a 1-dimensional \mathbb{Q} -lattice can always be written in the form

$$(3.13) \quad (\Lambda, \phi) = (\lambda \mathbb{Z}, \lambda \rho)$$

for some $\lambda > 0$ and some

$$(3.14) \quad \rho \in \text{Hom}(\mathbb{Q}/\mathbb{Z}, \mathbb{Q}/\mathbb{Z}) = \varprojlim \mathbb{Z}/n\mathbb{Z} = \hat{\mathbb{Z}}.$$

Thus, the set of 1-dimensional \mathbb{Q} -lattices up to scaling can be identified with $\hat{\mathbb{Z}}$. The invertible lattices correspond to the elements of $\hat{\mathbb{Z}}^*$, which in turn is identified with $\text{GL}_1^+(\mathbb{Q}) \backslash \text{GL}_1(\mathbb{A}_f)$.

The quotient (3.12) can be thought of geometrically as the Shimura variety associated to the *cyclotomic tower* (cf. [31]). This is the tower \mathcal{V} of arithmetic varieties over $V = \text{Spec}(\mathbb{Z})$, with $V_n = \text{Spec}(\mathbb{Z}[\zeta_n])$, where ζ_n is a primitive n -th root of unity. The group of deck transformations is $\text{Aut}_V(V_n) = \text{GL}_1(\mathbb{Z}/n\mathbb{Z})$, so that the group of deck transformations of the tower is the projective limit

$$(3.15) \quad \text{Aut}_V(\mathcal{V}) = \varprojlim_n \text{Aut}_V(V_n) = \text{GL}_1(\hat{\mathbb{Z}}).$$

If, instead of invertible \mathbb{Q} -lattices up to scale, we consider the set of commensurability classes of all 1-dimensional \mathbb{Q} -lattices up to scale, we find a noncommutative version of the Shimura variety (3.12) and of the cyclotomic tower. This is described as the quotient

$$(3.16) \quad Sh^{(nc)}(\text{GL}_1, \{\pm 1\}) := \text{GL}_1(\mathbb{Q}) \backslash (\mathbb{A}_f \times \{\pm 1\}) = \text{GL}_1(\mathbb{Q}) \backslash \mathbb{A}^\cdot / \mathbb{R}_+^*,$$

where $\mathbb{A}^\cdot := \mathbb{A}_f \times \mathbb{R}^*$ are the adèles of \mathbb{Q} with invertible archimedean component.

The corresponding noncommutative algebra of coordinates is given by the crossed product (cf. [56])

$$(3.17) \quad C_0(\mathbb{A}_f) \rtimes \mathbb{Q}_+^*.$$

One obtains an equivalent description of the noncommutative space (3.16), starting from the description (3.13) of 1-dimensional \mathbb{Q} -lattices. The commensurability relation is implemented by the action of $\mathbb{N}^\times = \mathbb{Z}_{>0}$ by

$$(3.18) \quad \alpha_n(f)(\rho) = \begin{cases} f(n^{-1}\rho) & \rho \in n\hat{\mathbb{Z}} \\ 0 & \text{otherwise.} \end{cases}$$

Thus, the noncommutative algebra of coordinates of the space of commensurability classes of 1-dimensional \mathbb{Q} -lattices up to scaling can be identified with the semigroup crossed product

$$(3.19) \quad \mathcal{A}_1 := C^*(\mathbb{Q}/\mathbb{Z}) \rtimes \mathbb{N}^\times,$$

FIGURE 3. Phasors with $\mathbb{Z}/6\mathbb{Z}$ discretization

where we have identified

$$(3.20) \quad C(\hat{\mathbb{Z}}) \simeq C^*(\mathbb{Q}/\mathbb{Z}),$$

since $\hat{\mathbb{Z}}$ is the Pontrjagin dual of \mathbb{Q}/\mathbb{Z} . The algebra (3.19) is Morita equivalent to the algebra (3.17) (*cf.* [56]).

The algebra (3.19) is isomorphic to the algebra considered in the work of Bost–Connes [8], which was obtained there as a Hecke algebra for the inclusion $\Gamma_0 \subset \Gamma$ of the pair of groups $(\Gamma_0, \Gamma) = (P_{\mathbb{Z}}, P_{\mathbb{Q}})$, where P is the $ax + b$ group. These have the property that the left Γ_0 orbits of any $\gamma \in \Gamma/\Gamma_0$ are finite (same for right orbits on the left coset). The ratio of the lengths of left and right Γ_0 orbits determines a canonical time evolution σ_t on the algebra (*cf.* [8]).

The algebra of the Bost–Connes system has an explicit presentation in terms of two sets of operators. The first type consists of *phase operators* $e(r)$, parameterized by elements $r \in \mathbb{Q}/\mathbb{Z}$. These phase operators can be represented on the Fock space generated by occupation numbers $|n\rangle$ as the operators

$$(3.21) \quad e(r)|n\rangle = \alpha(\zeta_r^n)|n\rangle.$$

Here we denote by $\zeta_{a/b} = \zeta_b^a$ the *abstract* roots of unity generating \mathbb{Q}^{cycl} and by $\alpha : \mathbb{Q}^{cycl} \hookrightarrow \mathbb{C}$ an embedding that identifies \mathbb{Q}^{cycl} with the subfield of \mathbb{C} generated by the *concrete* roots of unity.

These are the phase operators used in the theory of quantum optics and optical coherence to model the phase quantum-mechanically (*cf.* [60] [61]), as well as to model the *phasors* in quantum computing. They are based on the choice of a certain scale N at which the phase is discretized (Figure 3). Namely, the quantized optical phase is defined

as a state

$$|\theta_{m,N}\rangle = e\left(\frac{m}{N+1}\right) \cdot v_N,$$

where v_N is a superposition of occupation states

$$v_N = \frac{1}{(N+1)^{1/2}} \sum_{n=0}^N |n\rangle.$$

One needs then to ensure that the results are consistent over changes of scale.

The other operators that generate the Bost–Connes algebra can be thought of as implementing the changes of scales in the optical phases in a consistent way. These operators are isometries μ_n parameterized by positive integers $n \in \mathbb{N}^\times = \mathbb{Z}_{>0}$. The changes of scale are described by the action of the μ_n on the $e(r)$ by

$$(3.22) \quad \mu_n e(r) \mu_n^* = \frac{1}{n} \sum_{ns=r} e(s).$$

In addition to this compatibility condition, the operators $e(r)$ and μ_n satisfy other simple relations.

These give a presentation of the algebra of the BC system of the form ([8], [55]):

- $\mu_n^* \mu_n = 1$, for all $n \in \mathbb{N}^\times$,
- $\mu_k \mu_n = \mu_{kn}$, for all $k, n \in \mathbb{N}^\times$,
- $e(0) = 1$, $e(r)^* = e(-r)$, and $e(r)e(s) = e(r+s)$, for all $r, s \in \mathbb{Q}/\mathbb{Z}$,
- For all $n \in \mathbb{N}^\times$ and all $r \in \mathbb{Q}/\mathbb{Z}$, the relation (3.22) holds.

This shows that the Bost–Connes algebra is isomorphic to the algebra \mathcal{A}_1 of (3.19).

In terms of this explicit presentation, the time evolution is of the form

$$(3.23) \quad \sigma_t(\mu_n) = n^{it} \mu_n, \quad \sigma_t(e(r)) = e(r).$$

The space (3.16) can be compactified by replacing \mathbb{A}^\times by \mathbb{A} , as in [22]. This gives the quotient

$$(3.24) \quad \overline{Sh^{(nc)}}(\mathrm{GL}_1, \{\pm 1\}) = \mathrm{GL}_1(\mathbb{Q}) \backslash \mathbb{A} / \mathbb{R}_+^*.$$

This compactification consists of adding the trivial lattice (with a possibly nontrivial \mathbb{Q} -structure).

The dual space to (3.24), under the duality of type II and type III factors introduced in Connes' thesis, is a principal \mathbb{R}_+^* -bundle over (3.24), whose noncommutative algebra of coordinates is obtained from

the algebra of (3.24) by taking the crossed product by the time evolution σ_t . The space obtained this way is the space of adèle classes

$$(3.25) \quad \mathcal{L}_1 = \mathrm{GL}_1(\mathbb{Q}) \backslash \mathbb{A} \rightarrow \mathrm{GL}_1(\mathbb{Q}) \backslash \mathbb{A} / \mathbb{R}_+^*$$

that gives the spectral realization of zeros of the Riemann ζ function in [22]. Passing to this dual space corresponds to considering commensurability classes of 1-dimensional \mathbb{Q} -lattices (no longer up to scaling).

2.1. Structure of KMS states. The Bost–Connes algebra \mathcal{A}_1 has irreducible representations on the Hilbert space $\mathcal{H} = \ell^2(\mathbb{N}^\times)$. These are parameterized by elements $\alpha \in \hat{\mathbb{Z}}^* = \mathrm{GL}_1(\hat{\mathbb{Z}})$. Any such element defines an embedding $\alpha : \mathbb{Q}^{cycl} \hookrightarrow \mathbb{C}$ and the corresponding representation is of the form

$$(3.26) \quad \begin{aligned} \pi_\alpha(e(r)) \epsilon_k &= \alpha(\zeta_r^k) \epsilon_k \\ \pi_\alpha(\mu_n) \epsilon_k &= \epsilon_{nk} \end{aligned}$$

The Hamiltonian implementing the time evolution (3.18) on \mathcal{H} is

$$(3.27) \quad H \epsilon_k = \log k \epsilon_k$$

Thus, the partition function of the Bost–Connes system is the Riemann zeta function

$$(3.28) \quad Z(\beta) = \mathrm{Tr} (e^{-\beta H}) = \sum_{k=1}^{\infty} k^{-\beta} = \zeta(\beta).$$

Bost and Connes showed in [8] that KMS states have the following structure, with a phase transition at $\beta = 1$.

- In the range $\beta \leq 1$ there is a unique KMS_β state. Its restriction to $\mathbb{Q}[\mathbb{Q}/\mathbb{Z}]$ is of the form

$$\varphi_\beta(e(a/b)) = b^{-\beta} \prod_{p \text{ prime}, p|b} \frac{1 - p^{\beta-1}}{1 - p^{-1}}.$$

- For $1 < \beta \leq \infty$ the set of extremal KMS states \mathcal{E}_β can be identified with $\hat{\mathbb{Z}}^*$. It has a free and transitive action of this group induced by an action on \mathcal{A} by automorphisms. The extremal KMS_β state corresponding to $\alpha \in \hat{\mathbb{Z}}^*$ is of the form

$$(3.29) \quad \varphi_{\beta,\alpha}(x) = \frac{1}{\zeta(\beta)} \mathrm{Tr} (\pi_\alpha(x) e^{-\beta H}).$$

- At $\beta = \infty$ the Galois group $\mathrm{Gal}(\mathbb{Q}^{cycl}/\mathbb{Q})$ acts on the values of states $\varphi \in \mathcal{E}_\infty$ on an arithmetic subalgebra $\mathcal{A}_{1,\mathbb{Q}} \subset \mathcal{A}_1$. These have the property that $\varphi(\mathcal{A}_{1,\mathbb{Q}}) \subset \mathbb{Q}^{cycl}$ and that the isomorphism (class field theory isomorphism) $\theta : \mathrm{Gal}(\mathbb{Q}^{cycl}/\mathbb{Q}) \xrightarrow{\cong} \hat{\mathbb{Z}}^*$

intertwines the Galois action on values with the action of $\hat{\mathbb{Z}}^*$ by symmetries, namely,

$$(3.30) \quad \gamma^{-1} \varphi(x) = \varphi(\theta(\gamma) x),$$

for all $\varphi \in \mathcal{E}_\infty$, for all $\gamma \in \text{Gal}(\mathbb{Q}^{cycl}/\mathbb{Q})$ and for all $x \in \mathcal{A}_\mathbb{Q}$.

Here the arithmetic subalgebra $\mathcal{A}_{1,\mathbb{Q}}$ can be taken to be the algebra over \mathbb{Q} generated by the $e(r)$ and the μ_n, μ_n^* . This \mathbb{Q} -algebra can also be obtained (as shown in [29]) as the algebra generated by the μ_n, μ_n^* and by homogeneous functions of weight zero on 1-dim \mathbb{Q} -lattices obtained as a normalization of the functions

$$(3.31) \quad \epsilon_{k,a}(\Lambda, \phi) = \sum_{y \in \Lambda + \phi(a)} y^{-k}$$

by covolume. Namely, one considers the functions $e_{k,a} := c^k \epsilon_{k,a}$, where $c(\Lambda)$ is proportional to the covolume $|\Lambda|$ and satisfies

$$(2\pi\sqrt{-1}) c(\mathbb{Z}) = 1.$$

The choice of an ‘‘arithmetic subalgebra’’ corresponds to endowing the noncommutative space \mathcal{A} with an arithmetic structure. The subalgebra corresponds to the rational functions and the values of KMS_∞ states at elements of this subalgebra should be thought of as values of ‘‘rational functions’’ at the classical points of the noncommutative space (*cf.* [31]).

3. Noncommutative Geometry and Hilbert’s 12th problem

The most remarkable arithmetic feature of the result of Bost–Connes recalled above is the Galois action on the ground states of the system. First of all, the fact that the Galois action on the values of states would preserve positivity (*i.e.* would give values of other states) is a very unusual property. Moreover, the values of extremal ground states on elements of the rational subalgebra generate the maximal abelian extension $\mathbb{Q}^{ab} = \mathbb{Q}^{cycl}$ of \mathbb{Q} . The explicit action of the Galois group $\text{Gal}(\mathbb{Q}^{ab}/\mathbb{Q}) \simeq \text{GL}_1(\hat{\mathbb{Z}})$ is given by automorphism of the system $(\mathcal{A}_1, \sigma_t)$. Namely, the class field theory isomorphism intertwines the two actions of the idèles class group, as symmetry group of the system, and of the Galois group, as permutations of the expectation values of the rational observables.

In general, the main theorem of class field theory provides a classification of finite abelian extensions of a local or global field \mathbb{K} in terms of subgroups of a locally compact abelian group canonically associated to the field. This is the multiplicative group $\mathbb{K}^* = \text{GL}_1(\mathbb{K})$ in the local

nonarchimedean case, while in the global case it is the quotient $C_{\mathbb{K}}/D_{\mathbb{K}}$ of the idèle class group $C_{\mathbb{K}}$ by the connected component of the identity.

Hilbert’s 12th problem can be formulated as the question of providing an explicit set of generators of the maximal abelian extension \mathbb{K}^{ab} of a number field \mathbb{K} , inside an algebraic closure $\bar{\mathbb{K}}$, and of the action of the Galois group $\text{Gal}(\mathbb{K}^{ab}/\mathbb{K})$. The maximal abelian extension \mathbb{K}^{ab} of \mathbb{K} has the property that

$$\text{Gal}(\mathbb{K}^{ab}/\mathbb{K}) = \text{Gal}(\bar{\mathbb{K}}/\mathbb{K})^{ab}.$$

The result that motivated Hilbert’s formulation of the explicit class field theory problem, is the Kronecker–Weber theorem, namely the already mentioned case of the explicit class field theory of $\mathbb{K} = \mathbb{Q}$. In this case, the maximal abelian extension of \mathbb{Q} can be identified with the cyclotomic field \mathbb{Q}^{cycl} . Equivalently, one can say that the torsion points of the multiplicative group \mathbb{C}^* (*i.e.* the roots of unity) generate $\mathbb{Q}^{ab} \subset \mathbb{C}$.

Remarkably, the only other case for number fields where this program has been carried out completely is that of imaginary quadratic fields, where the construction relies on the theory of elliptic curves with complex multiplication, and on the Galois theory of the field of modular functions (*cf. e.g.* the survey [90]).

Some generalizations of the original result of Bost–Connes to other global fields (number fields and function fields) were obtained by Harari and Leichtnam [49], P. Cohen [14], Arledge, Laca and Raeburn [3]. A more detailed account of various results related to the BC system and generalizations is given in the “further developments” section of [29]. Because of this close relation to Hilbert’s 12th problem, it is clear that finding generalizations of the Bost–Connes system to other number fields is a very difficult problem, hence it is not surprising that, so far, these constructions have not fully recovered the Galois properties of the ground states of the BC system in the generalized setting.

The strongest form of the result one may wish to obtain in this direction can be formulated as follows.

Given a number field \mathbb{K} , we let $\mathbb{A}_{\mathbb{K}}$ denote the adèles of \mathbb{K} and we let $\mathbb{A}_{\mathbb{K}}^* = \text{GL}_1(\mathbb{A}_{\mathbb{K}})$ be the group of idèles of \mathbb{K} . As above, we write $C_{\mathbb{K}}$ for the group of idèles classes $C_{\mathbb{K}} = \mathbb{A}_{\mathbb{K}}^*/\mathbb{K}^*$ and $D_{\mathbb{K}}$ for the connected component of the identity in $C_{\mathbb{K}}$.

One wishes to construct a C^* -dynamical system (\mathcal{A}, σ_t) and an “arithmetic” subalgebra $\mathcal{A}_{\mathbb{K}}$, which satisfy the following properties:

- (1) The idèles class group $G = C_{\mathbb{K}}/D_{\mathbb{K}}$ acts by symmetries on (\mathcal{A}, σ_t) preserving the subalgebra $\mathcal{A}_{\mathbb{K}}$.
- (2) The states $\varphi \in \mathcal{E}_{\infty}$, evaluated on elements of $\mathcal{A}_{\mathbb{K}}$, satisfy:

- $\varphi(a) \in \bar{\mathbb{K}}$, the algebraic closure of \mathbb{K} in \mathbb{C} ;
- the elements of $\{\varphi(a) : a \in \mathcal{A}_{\mathbb{K}}\}$, for $\varphi \in \mathcal{E}_{\infty}$ generate \mathbb{K}^{ab} .

(3) The class field theory isomorphism

$$\theta : C_{\mathbb{K}}/D_{\mathbb{K}} \xrightarrow{\simeq} \text{Gal}(\mathbb{K}^{ab}/\mathbb{K})$$

intertwines the actions,

$$(3.32) \quad \alpha^{-1} \circ \varphi = \varphi \circ \theta^{-1}(\alpha),$$

for all $\alpha \in \text{Gal}(\mathbb{K}^{ab}/\mathbb{K})$ and for all $\varphi \in \mathcal{E}_{\infty}$.

This may provide a possible new approach, via noncommutative geometry, to the explicit class field theory problem.

Given a number field \mathbb{K} with $[\mathbb{K} : \mathbb{Q}] = n$, there is an embedding $\mathbb{K}^* \hookrightarrow GL_n(\mathbb{Q})$ of its multiplicative group in $GL_n(\mathbb{Q})$. Such embedding induces an embedding of $GL_1(\mathbb{A}_{\mathbb{K},f})$ into $GL_n(\mathbb{A}_f)$, where $\mathbb{A}_{\mathbb{K},f} = \mathbb{A}_f \otimes \mathbb{K}$ are the finite adèles of \mathbb{K} .

This suggests that a possible strategy to approach the problem stated above may be to first study quantum statistical mechanical systems corresponding to GL_n analogs of the Bost–Connes system.

The main result of the joint work of Alain Connes and the author in [29] is the construction of such system in the GL_2 case and the analysis of the arithmetic properties of its KMS states. In the case of GL_2 , one sees that the geometry of modular curves and the algebra of modular forms appear naturally. This leads to a formulation of a quantum statistical mechanical system related to the explicit class field theory of imaginary quadratic fields [31].

The first case for which there is not yet a complete solution to the explicit class field theory problem is the case of real quadratic fields, $\mathbb{K} = \mathbb{Q}(\sqrt{d})$, for some positive integer d . It is natural to ask whether the approach outlined above, based on noncommutative geometry, may provide any new information on this case. Recent work of Manin [62] [63] suggests a close relation between the real quadratic case and noncommutative geometry. We will discuss the possible relation between his approach and the GL_2 -system.

4. The GL_2 system

In this section we will describe the main features of the GL_2 analog of the Bost–Connes system, according to the results of [29].

We can start with the same geometric approach in terms of Shimura varieties (*cf.* [31], [30]) that we used above to introduce the BC system.

The Shimura variety associated to the tower of modular curves is described by the adèlic quotient

$$(3.33) \quad \begin{aligned} Sh(\mathrm{GL}_2, \mathbb{H}^\pm) &= \mathrm{GL}_2(\mathbb{Q}) \backslash (\mathrm{GL}_2(\mathbb{A}_f) \times \mathbb{H}^\pm) \\ &= \mathrm{GL}_2^+(\mathbb{Q}) \backslash (\mathrm{GL}_2(\mathbb{A}_f) \times \mathbb{H}) = \mathrm{GL}_2^+(\mathbb{Q}) \backslash \mathrm{GL}_2(\mathbb{A}) / \mathbb{C}^*. \end{aligned}$$

The tower of modular curves (*cf.* [31]) has base $V = \mathbb{P}^1$ over \mathbb{Q} and $V_n = X(n)$ the modular curve corresponding to the principal congruence subgroup $\Gamma(n)$. The automorphisms of the projection $V_n \rightarrow V$ are given by $\mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})/\{\pm 1\}$, so that the group of deck transformations of the tower \mathcal{V} is in this case of the form

$$\mathrm{Aut}_V(\mathcal{V}) = \varprojlim_n \mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})/\{\pm 1\} = \mathrm{GL}_2(\hat{\mathbb{Z}})/\{\pm 1\}.$$

The inverse limit $\varprojlim \Gamma \backslash \mathbb{H}$ over congruence subgroups $\Gamma \subset \mathrm{SL}(2, \mathbb{Z})$ gives a connected component of (3.33), while by taking congruence subgroups in $\mathrm{SL}(2, \mathbb{Q})$ one obtains the adèlic version $Sh(\mathrm{GL}_2, \mathbb{H}^\pm)$. The simple reason why it is necessary to pass to the nonconnected case is the following. The varieties in the tower are arithmetic varieties defined over number fields. However, the number field typically changes along the levels of the tower (V_n is defined over the cyclotomic field $\mathbb{Q}(\zeta_n)$). Passing to nonconnected Shimura varieties allows for the definition of a canonical model where the whole tower is defined over the same number field.

The quotient (3.33) parameterizes invertible 2-dimensional \mathbb{Q} -lattices up to scaling (*cf.* [78]). When, instead of restricting to the invertible case, we consider commensurability classes of 2-dimensional \mathbb{Q} -lattices up to scaling, we obtain a noncommutative space whose classical points are the Shimura variety (3.33). More precisely, we have the following (*cf.* [31]):

LEMMA 4.1. *The space of commensurability classes of 2-dimensional \mathbb{Q} -lattices up to scaling is described by the quotient*

$$(3.34) \quad Sh^{(nc)}(\mathrm{GL}_2, \mathbb{H}^\pm) := \mathrm{GL}_2(\mathbb{Q}) \backslash (M_2(\mathbb{A}_f) \times \mathbb{H}^\pm).$$

Any 2-dimensional \mathbb{Q} -lattice can be written in the form

$$(\Lambda, \phi) = (\lambda(\mathbb{Z} + \mathbb{Z}\tau), \lambda\rho),$$

for some $\lambda \in \mathbb{C}^*$, some $\tau \in \mathbb{H}$, and some

$$\rho \in M_2(\hat{\mathbb{Z}}) = \mathrm{Hom}(\mathbb{Q}^2/\mathbb{Z}^2, \mathbb{Q}^2/\mathbb{Z}^2).$$

Thus, the space of 2-dimensional \mathbb{Q} -lattices up to the scale factor $\lambda \in \mathbb{C}^*$ and up to isomorphisms, is given by

$$(3.35) \quad M_2(\hat{\mathbb{Z}}) \times \mathbb{H} \quad \text{mod } \Gamma = \text{SL}(2, \mathbb{Z}).$$

The commensurability relation is implemented by the partially defined action of $GL_2^+(\mathbb{Q})$ on this space, given by

$$g(\rho, z) = (g\rho, g(z)),$$

where $g(z)$ denotes action as fractional linear transformation.

Equivalently, the data (Λ, ϕ) of a \mathbb{Q} -lattice in \mathbb{C} are equivalent to data (E, η) of an elliptic curve $E = \mathbb{C}/\Lambda$ and an \mathbb{A}_f -homomorphism

$$(3.36) \quad \eta : \mathbb{Q}^2 \otimes \mathbb{A}_f \rightarrow \Lambda \otimes \mathbb{A}_f,$$

where $\Lambda \otimes \mathbb{A}_f = (\Lambda \otimes \hat{\mathbb{Z}}) \otimes \mathbb{Q}$, with

$$(3.37) \quad \Lambda \otimes \hat{\mathbb{Z}} = \varprojlim_n \Lambda/n\Lambda,$$

and $\Lambda/n\Lambda = E[n]$ the n th torsion of E . Since the \mathbb{Q} -lattices need not be invertible, we do not require that η be an \mathbb{A}_f -isomorphism (*cf.* [78]).

The commensurability relation between \mathbb{Q} -lattices corresponds to the equivalence $(E, \eta) \sim (E', \eta')$ given by an isogeny $g : E \rightarrow E'$ and $\eta' = (g \otimes 1) \circ \eta$. Namely, the equivalence classes can be identified with the quotient of $M_2(\mathbb{A}_f) \times \mathbb{H}^\pm$ by the action of $GL_2(\mathbb{Q})$, $(\rho, z) \mapsto (g\rho, g(z))$.

To associate a quantum statistical mechanical system to the space of commensurability classes of 2-dimensional \mathbb{Q} -lattices up to scaling, it is convenient to use the description (3.35). Then one can consider as noncommutative algebra of coordinates the convolution algebra of continuous compactly supported functions on the quotient of the space

$$(3.38) \quad \mathcal{U} := \{(g, \rho, z) \in GL_2^+(\mathbb{Q}) \times M_2(\hat{\mathbb{Z}}) \times \mathbb{H} \mid g\rho \in M_2(\hat{\mathbb{Z}})\}$$

by the action of $\Gamma \times \Gamma$,

$$(3.39) \quad (g, \rho, z) \mapsto (\gamma_1 g \gamma_2^{-1}, \gamma_2 z).$$

One endows this algebra with the convolution product

$$(3.40) \quad (f_1 * f_2)(g, \rho, z) = \sum_{s \in \Gamma \backslash GL_2^+(\mathbb{Q}) : s\rho \in M_2(\hat{\mathbb{Z}})} f_1(gs^{-1}, s\rho, s(z)) f_2(s, \rho, z)$$

and the involution $f^*(g, \rho, z) = \overline{f(g^{-1}, g\rho, g(z))}$.

The time evolution is given by

$$(3.41) \quad \sigma_t(f)(g, \rho, z) = \det(g)^{it} f(g, \rho, z).$$

For $\rho \in M_2(\hat{\mathbb{Z}})$ let

$$(3.42) \quad G_\rho := \{g \in \mathrm{GL}_2^+(\mathbb{Q}) : g\rho \in M_2(\hat{\mathbb{Z}})\}$$

and consider the Hilbert space $\mathcal{H}_\rho = \ell^2(\Gamma \backslash G_\rho)$.

A 2-dimensional \mathbb{Q} -lattice $L = (\Lambda, \phi) = (\rho, z)$ determines a representation of the Hecke algebra by bounded operators on \mathcal{H}_ρ , setting

$$(3.43) \quad (\pi_L(f)\xi)(g) = \sum_{s \in \Gamma \backslash G_\rho} f(gs^{-1}, s\rho, s(z)) \xi(s).$$

In particular, when the \mathbb{Q} -lattice $L = (\Lambda, \phi)$ is invertible one obtains

$$\mathcal{H}_\rho \cong \ell^2(\Gamma \backslash M_2^+(\mathbb{Z})).$$

In this case, the Hamiltonian implementing the time evolution (3.41) is given by the operator

$$(3.44) \quad H \epsilon_m = \log \det(m) \epsilon_m.$$

Thus, in the special case of invertible \mathbb{Q} -lattices (3.43) yields a *positive energy* representation. In general for \mathbb{Q} -lattices which are not commensurable to an invertible one, the corresponding Hamiltonian H is not bounded below.

The Hecke algebra (3.40) admits a C^* -algebra completion \mathcal{A}_2 , where the norm is the sup over all representations π_L .

The partition function for this GL_2 system is given by

$$(3.45) \quad Z(\beta) = \sum_{m \in \Gamma \backslash M_2^+(\mathbb{Z})} \det(m)^{-\beta} = \sum_{k=1}^{\infty} \sigma(k) k^{-\beta} = \zeta(\beta)\zeta(\beta-1),$$

where $\sigma(k) = \sum_{d|k} d$. This suggests the fact that one expects two phase transitions to take place, at $\beta = 1$ and $\beta = 2$, respectively.

The set of components of $Sh(\mathrm{GL}_2, \mathbb{H}^\pm)$ is given by

$$(3.46) \quad \pi_0(Sh(\mathrm{GL}_2, \mathbb{H}^\pm)) = Sh(\mathrm{GL}_1, \{\pm 1\}).$$

Similarly, on the level of the corresponding noncommutative spaces (3.34) and (3.16), the identification (3.46) gives the compatibility between the GL_1 and the GL_2 system (*cf.* [31]). At the level of the classical commutative spaces, this is given by the map

$$(3.47) \quad \det \times \mathrm{sign} : Sh(\mathrm{GL}_2, \mathbb{H}^\pm) \rightarrow Sh(\mathrm{GL}_1, \{\pm 1\}),$$

which corresponds in fact to passing to the set π_0 of connected components.

4.1. KMS states of the GL_2 -system. The main result of [29] on the structure of KMS states is the following.

THEOREM 4.2. *The KMS_β states of the GL_2 -system have the following properties:*

- (1) *In the range $\beta \leq 1$ there are no KMS states.*
- (2) *In the range $\beta > 2$ the set of extremal KMS states is given by the classical Shimura variety*

$$(3.48) \quad \mathcal{E}_\beta \cong GL_2(\mathbb{Q}) \backslash GL_2(\mathbb{A}) / \mathbb{C}^*.$$

This shows that the extremal KMS states at sufficiently low temperature are parameterized by the invertible \mathbb{Q} -lattices. The explicit expression for these extremal KMS_β states is obtained as

$$(3.49) \quad \varphi_{\beta,L}(f) = \frac{1}{Z(\beta)} \sum_{m \in \Gamma \backslash M_2^+(\mathbb{Z})} f(1, m\rho, m(z)) \det(m)^{-\beta}$$

where $L = (\rho, z)$ is an invertible \mathbb{Q} -lattice.

As the temperature rises, and we let $\beta \rightarrow 2$ from above, all the different phases of the system merge, which is strong evidence for the fact that in the intermediate range $1 < \beta \leq 2$ the system should have only a single KMS state.

The symmetry group of \mathcal{A}_2 (including both automorphisms and endomorphisms) can be identified with the group

$$(3.50) \quad GL_2(\mathbb{A}_f) = GL_2^+(\mathbb{Q})GL_2(\hat{\mathbb{Z}}).$$

Here the group $GL_2(\hat{\mathbb{Z}})$ acts by automorphisms,

$$(3.51) \quad \theta_\gamma(f)(g, \rho, z) = f(g, \rho\gamma, z),$$

as the group of deck transformations of coverings of modular curves.

The novelty with respect to the BC case is that we also have an action of $GL_2^+(\mathbb{Q})$ by endomorphisms

$$(3.52) \quad \theta_m(f)(g, \rho, z) = \begin{cases} f(g, \rho\tilde{m}^{-1}, z) & \rho \in m M_2(\hat{\mathbb{Z}}) \\ 0 & \text{otherwise} \end{cases}$$

where $\tilde{m} = \det(m)m^{-1}$.

The subgroup $\mathbb{Q}^* \hookrightarrow GL_2(\mathbb{A}_f)$ acts by inner, hence the group of symmetries of the set of extremal states \mathcal{E}_β is of the form

$$(3.53) \quad S = \mathbb{Q}^* \backslash GL_2(\mathbb{A}_f).$$

In the case of \mathcal{E}_∞ states (defined as weak limits) the action of $GL_2^+(\mathbb{Q})$ is more subtle to define. In fact, (3.52) does not directly induce a nontrivial action on \mathcal{E}_∞ . However, there is a nontrivial action

induced by the action on \mathcal{E}_β states for sufficiently large β . The action on the KMS_∞ states is obtained by a “warming up and cooling down procedure”, as in (3.10) and (3.11).

Finally, the Galois action on the extremal KMS_∞ states is described by the following result [29].

THEOREM 4.3. *There exists an arithmetic subalgebra $\mathcal{A}_{2,\mathbb{Q}}$ of unbounded multiplier of the C^* -algebra \mathcal{A}_2 , such that the following holds. For $\varphi_{\infty,L} \in \mathcal{E}_\infty$ with $L = (\rho, \tau)$ generic, the values on arithmetic elements satisfy*

$$(3.54) \quad \varphi_{\infty,L}(\mathcal{A}_{2,\mathbb{Q}}) \subset F_\tau,$$

where F_τ is the embedding of the modular field in \mathbb{C} given by evaluation at $\tau \in \mathbb{H}$. There is an isomorphism

$$(3.55) \quad \theta_\varphi : \text{Gal}(F_\tau/\mathbb{Q}) \xrightarrow{\cong} \mathbb{Q}^* \backslash \text{GL}_2(\mathbb{A}_f),$$

that intertwines the Galois action on the values of the state with the action of symmetries,

$$(3.56) \quad \gamma^{-1} \varphi(f) = \varphi(\theta_\varphi(\gamma)f), \quad \forall f \in \mathcal{A}_{2,\mathbb{Q}}, \quad \forall \gamma \in \text{Gal}(F_\tau/\mathbb{Q}).$$

Here recall that the modular field F is the field of modular functions over \mathbb{Q}^{ab} , namely the union of the fields F_N of modular functions of level N rational over the cyclotomic field $\mathbb{Q}(\zeta_n)$, that is, such that the q -expansion in powers of $q^{1/N} = \exp(2\pi i\tau/N)$ has all coefficients in $\mathbb{Q}(e^{2\pi i/N})$.

It has explicit generators given by the Fricke functions ([88], [57]). If \wp is the Weierstrass \wp -function, which gives the parameterization

$$z \mapsto (1, \wp(z; \tau, 1), \wp'(z; \tau, 1))$$

of the elliptic curve

$$y^2 = 4x^3 - g_2(\tau)x - g_3(\tau)$$

by the quotient $\mathbb{C}/(\mathbb{Z} + \mathbb{Z}\tau)$, then the Fricke functions are homogeneous functions of 1-dimensional lattices of weight zero, parameterized by $v \in \mathbb{Q}^2/\mathbb{Z}^2$, of the form

$$(3.57) \quad f_v(\tau) = -2^7 3^5 \frac{g_2(\tau)g_3(\tau)}{\Delta(\tau)} \wp(\lambda_\tau(v); \tau, 1),$$

where $\Delta = g_2^3 - 27g_3^2$ is the discriminant and $\lambda_\tau(v) := v_1\tau + v_2$.

For generic τ (such that $j(\tau)$ is transcendental), evaluation of the modular functions at the point $\tau \in \mathbb{H}$ gives an embedding $F_\tau \hookrightarrow \mathbb{C}$. There is a corresponding isomorphism

$$(3.58) \quad \theta_\tau : \text{Gal}(F_\tau/\mathbb{Q}) \xrightarrow{\cong} \text{Aut}(F).$$

The isomorphism (3.55) is given by

$$(3.59) \quad \theta_\varphi(\gamma) = \rho^{-1} \theta_\tau(\gamma) \rho,$$

for θ_τ as in (3.58). In fact, the group of automorphisms $\mathrm{Aut}(F)$ has a completely explicit description, due to a result of Shimura [88], which identifies it with the quotient

$$\mathrm{Aut}(F) \cong \mathbb{Q}^* \backslash \mathrm{GL}_2(\mathbb{A}_f).$$

We still need to explain what is the arithmetic subalgebra that appears in Theorem 4.3.

We consider continuous functions on the quotient of (3.38) by the action (3.39), which have finite support in the variable $g \in \Gamma \backslash \mathrm{GL}_2^+(\mathbb{Q})$. For convenience we adopt the notation

$$f_{(g,\rho)}(z) = f(g, \rho, z)$$

so that $f_{(g,\rho)} \in C(\mathbb{H})$. Let $p_N : M_2(\hat{\mathbb{Z}}) \rightarrow M_2(\mathbb{Z}/N\mathbb{Z})$ be the canonical projection. We say that f is of level N if

$$f_{(g,\rho)} = f_{(g,p_N(\rho))} \quad \forall (g, \rho).$$

Then f is completely determined by the functions

$$f_{(g,m)} \in C(\mathbb{H}), \quad \text{for } m \in M_2(\mathbb{Z}/N\mathbb{Z}).$$

Notice that the invariance

$$f(g\gamma, \rho, z) = f(g, \gamma\rho, \gamma(z)),$$

for all $\gamma \in \Gamma$ and for all $(g, \rho, z) \in \mathcal{U}$, implies that we have

$$(3.60) \quad f_{(g,m)|_\gamma} = f_{(g,m)}, \quad \forall \gamma \in \Gamma(N) \cap g^{-1}\Gamma g.$$

so that f is invariant under a congruence subgroup.

Elements f of $\mathcal{A}_{2,\mathbb{Q}}$ are characterized by the following properties.

- The support of f in $\Gamma \backslash \mathrm{GL}_2^+(\mathbb{Q})$ is finite.
- The function f is of finite level with

$$f_{(g,m)} \in F \quad \forall (g, m).$$

- The function f satisfies the *cyclotomic condition*:

$$f_{(g,\alpha(u)m)} = \mathrm{cycl}(u) f_{(g,m)},$$

for all $g \in \mathrm{GL}_2^+(\mathbb{Q})$ diagonal and all $u \in \hat{\mathbb{Z}}^*$, with

$$\alpha(u) = \begin{pmatrix} u & 0 \\ 0 & 1 \end{pmatrix}.$$

Here $\text{cycl} : \hat{\mathbb{Z}}^* \rightarrow \text{Aut}(F)$ denotes the action of the Galois group $\hat{\mathbb{Z}}^* \simeq \text{Gal}(\mathbb{Q}^{ab}/\mathbb{Q})$ on the coefficients of the q -expansion in powers of $q^{1/N} = \exp(2\pi i\tau/N)$.

If we took only the first two conditions, this would allow the algebra $\mathcal{A}_{2,\mathbb{Q}}$ to contain the cyclotomic field $\mathbb{Q}^{ab} \subset \mathbb{C}$, but this would prevent the existence of states satisfying the desired Galois property. In fact, if the subalgebra contains scalar elements in \mathbb{Q}^{cycl} , the sought for Galois property would not be compatible with the \mathbb{C} -linearity of states. The cyclotomic condition then forces the spectrum of the elements of $\mathcal{A}_{2,\mathbb{Q}}$ to contain all Galois conjugates of any root of unity that appears in the coefficients of the q -series, so that elements of $\mathcal{A}_{2,\mathbb{Q}}$ cannot be scalars.

The algebra $\mathcal{A}_{2,\mathbb{Q}}$ defined by the properties above is a subalgebra of unbounded multipliers of \mathcal{A}_2 , which is globally invariant under the group of symmetries $\mathbb{Q}^* \backslash \text{GL}_2(\mathbb{A}_f)$.

5. Quadratic fields

The first essential step in the direction of generalizing the BC system to other number fields and exploring a possible approach to the explicit class field theory problem via noncommutative geometry is the construction of a system that recovers the explicit class field theory for imaginary quadratic fields $\mathbb{K} = \mathbb{Q}(\sqrt{-d})$, for d a positive integer. This case is being investigated as part of ongoing joint work of Alain Connes, Niranjan Ramachandran, and the author [31].

A system for imaginary quadratic fields can be constructed by considering 1-dimensional \mathbb{K} -lattices. These are lattices in \mathbb{K} with a homomorphism $\phi : \mathbb{K}/\mathcal{O} \rightarrow \mathbb{Q}\Lambda/\Lambda$, where \mathcal{O} is the ring of integers of \mathbb{K} . A choice of a generator $\tau \in \mathbb{H}$ such that $\mathbb{K} = \mathbb{Q}(\tau)$ realizes 1-dimensional \mathbb{K} -lattices as a particular set of 2-dimensional \mathbb{Q} -lattices. The commensurability relation for 1-dimensional \mathbb{K} -lattices can be defined as a commensurability of the underlying 2-dimensional \mathbb{Q} -lattices where the isomorphism is realized by multiplication by an element in \mathbb{K}^* , viewed as embedded in $\text{GL}_2^+(\mathbb{Q})$.

The set of commensurability classes of 1-dimensional \mathbb{K} -lattices up to scale is then described by the quotient

$$(3.61) \quad \mathbb{A}_{\mathbb{K},f}/\mathbb{K}^*,$$

where $\mathbb{A}_{\mathbb{K},f} = \mathbb{A}_f \otimes \mathbb{K}$ are the finite adèles of \mathbb{K} , while the set of invertible 1-dimensional \mathbb{K} -lattices up to scale can be identified with the idèle class group

$$(3.62) \quad C_{\mathbb{K}}/D_{\mathbb{K}} = \mathbb{A}_{\mathbb{K},f}^*/\mathbb{K}^*.$$

The noncommutative algebra of coordinates of the quotient (3.61) is obtained as in the case of the GL_2 -system as the convolution algebra of functions on

$$\mathcal{U}_{\mathbb{K}} = \{(x, \rho) \in \mathbb{K}^* \times \hat{\mathcal{O}} : x\rho \in \hat{\mathcal{O}}\},$$

with $\hat{\mathcal{O}} = \hat{\mathbb{Z}} \otimes \mathcal{O}$, endowed with the time evolution

$$(3.63) \quad \sigma_t(f)(x, \rho, \lambda) = N(x)^{-it} f(x, \rho, \lambda),$$

where $N : K^* \rightarrow \mathbb{Q}^*$ is the norm map.

This quantum statistical mechanical system has properties that are, in a sense, intermediate between the BC system and the GL_2 -system.

The symmetry group is the group of idèles classes $\mathbb{A}_{\mathbb{K},f}^*$, with the subgroup \mathbb{K}^* acting by inner, so that the induced action on KMS states is by the idèle class group (3.62). As in the case of the GL_2 -system, only the subgroup $\hat{\mathcal{O}}/\mathcal{O}^*$, with \mathcal{O}^* the group of units, acts by automorphisms, while the full action of $\mathbb{A}_{\mathbb{K},f}^*/\mathbb{K}^*$ also involves endomorphisms.

This, in particular, shows the appearance of the class number of \mathbb{K} , as one can see from the commutative diagram

$$(3.64) \quad \begin{array}{ccccccc} 1 & \longrightarrow & \hat{\mathcal{O}}^*/\mathcal{O}^* & \longrightarrow & \mathbb{A}_{\mathbb{K},f}^*/\mathbb{K}^* & \longrightarrow & \mathrm{Cl}(\mathcal{O}) \longrightarrow 1 \\ & & \downarrow \simeq & & \downarrow \simeq & & \downarrow \simeq \\ 1 & \longrightarrow & \mathrm{Gal}(\mathbb{K}^{ab}/H) & \longrightarrow & \mathrm{Gal}(\mathbb{K}^{ab}/\mathbb{K}) & \longrightarrow & \mathrm{Gal}(H/\mathbb{K}) \longrightarrow 1, \end{array}$$

where H is the Hilbert class field of \mathbb{K} , *i.e.*, its maximal abelian unramified extension. The ideal class group $\mathrm{Cl}(\mathcal{O})$ is naturally isomorphic to the Galois group $\mathrm{Gal}(H/\mathbb{K})$. The case of class number one is analogous to the BC system, as was already observed (*cf.* [49]).

The same definition of the arithmetic algebra $\mathcal{A}_{2,\mathbb{Q}}$ for the GL_2 -system provides a subalgebra of the system for the imaginary quadratic field \mathbb{K} . In fact, one considers functions in $\mathcal{A}_{2,\mathbb{Q}}$ whose finite support in the g variable lies in \mathbb{K}^* embedded in $\mathrm{GL}_2^+(\mathbb{Q})$, and then takes the restriction to the set of 1-dimensional \mathbb{K} -lattices, by evaluation at $\tau \in \mathbb{H}$ and restriction to $\rho \in \hat{\mathcal{O}}$, embedded in $M_2(\hat{\mathbb{Z}})$.

Notice that, because of the fact that the variable $z \in \mathbb{H}$ is now set to be $z = \tau$, we obtain a subalgebra as in the BC case and not an algebra of unbounded multipliers as in the GL_2 -case.

With this choice of the arithmetic subalgebra, one obtains a result analogous to Theorem 4.3. Namely, since now the 2-dimensional \mathbb{Q} -lattices $L = (\rho, \tau)$ we are considering have a fixed $\tau \in \mathbb{H} \cap \mathbb{K}$, we are no longer in the generic case of Theorem 4.3. For a CM point $\tau \in \mathbb{H} \cap \mathbb{K}$ evaluation of elements f in the modular field at τ no longer gives an

embedding. The image $F_\tau \subset \mathbb{C}$ is in this case a copy of the maximal abelian extension of \mathbb{K} (*cf.* [88])

$$(3.65) \quad F \rightarrow F_\tau \simeq \mathbb{K}^{ab} \subset \mathbb{C}.$$

The explicit action of the Galois group $\text{Gal}(\mathbb{K}^{ab}/\mathbb{K})$ is obtained through the action of automorphisms of the modular field via Shimura reciprocity [88], as described in the following diagram with exact rows:

$$(3.66) \quad \begin{array}{ccccccc} 1 & \longrightarrow & K^* & \longrightarrow & \text{GL}_1(\mathbb{A}_{K,f}) & \xrightarrow{\theta} & \text{Gal}(K^{ab}/K) \longrightarrow 1 \\ & & & & \downarrow q_\tau & & \\ 1 & \longrightarrow & \mathbb{Q}^* & \longrightarrow & \text{GL}_2(\mathbb{A}_f) & \xrightarrow{\sigma} & \text{Aut}(F) \longrightarrow 1. \end{array}$$

Here θ is the class field theory isomorphism and q_τ is the embedding determined by the choice of $\tau \in H$ with $\mathbb{K} = \mathbb{Q}(\tau)$. Thus, the explicit Galois action is given by

$$\theta(\gamma)(f(\tau)) = f^{\sigma(q_\tau(\gamma))}(\tau),$$

where $f \mapsto f^\alpha$ denotes the action of $\alpha \in \text{Aut}(F)$.

This provides the intertwining between the symmetries of the quantum statistical mechanical system and the Galois action on the image of states on the elements of the arithmetic subalgebra.

The structure of KMS states at positive temperatures is similar to the Bost–Connes case (*cf.* [31]).

The next fundamental question in the direction of generalizations of the BC system to other number fields is how to approach the more case of real quadratic fields. We give a brief outline of Manin’s ideas on real multiplication [62] [63], and suggest how they may combine with the GL_2 -system described above.

5.1. Real multiplication. Recently, Manin developed a theory of real multiplication for noncommutative tori [63], aimed at providing a setting, within noncommutative geometry, where to treat the problem of abelian extensions of real quadratic fields on a somewhat similar footing as the known case of imaginary quadratic fields, for which the theory of elliptic curves with complex multiplication provides the right geometric setup.

The first entry in the dictionary developed in [63] between elliptic curves with complex multiplication and noncommutative tori with real multiplication consists of a parallel between lattices and pseudolattices in \mathbb{C} ,

$$(\mathbb{C}, \text{lattice } \Lambda) \longleftrightarrow (\mathbb{R}, \text{pseudo-lattice } L).$$

By a pseudo-lattice one means the data of a free abelian group of rank two, with an injective homomorphism to a 1-dimensional complex vector space, such that the image lies in an oriented real line.

This aims at generalizing the well known equivalence between the category of elliptic curves and the category of lattices, realized by the period functor, to a setting that includes noncommutative tori.

As we have seen previously, any 2-dimensional lattice is, up to isomorphism, of the form $\Lambda_\tau = \mathbb{Z} + \mathbb{Z}\tau$, for $\tau \in \mathbb{C} \setminus \mathbb{R}$ and non-trivial morphisms between such lattices are given by the action of matrices $M_2(\mathbb{Z})$ by fractional linear transformations. Thus, the moduli space of lattices up to isomorphism is given by the quotient of $\mathbb{P}^1(\mathbb{C}) \setminus \mathbb{P}^1(\mathbb{R})$ by $\mathrm{PGL}_2(\mathbb{Z})$.

A pseudo-lattice is, up to isomorphism, of the form $L_\theta = \mathbb{Z} + \mathbb{Z}\theta$, for $\theta \in \mathbb{R} \setminus \mathbb{Q}$, and non-trivial morphisms of pseudo-lattices are again given by matrices in $M_2(\mathbb{Z})$ acting by fractional linear transformations on $\mathbb{P}^1(\mathbb{R})$. The moduli space of pseudo-lattices is given by the quotient of $\mathbb{P}^1(\mathbb{R})$ by the action of $\mathrm{PGL}(2, \mathbb{Z})$. Since the action does not give rise to a nice classical quotient, this moduli space should be treated as a noncommutative space.

As described at length in the previous chapter, the resulting space represents a component in the “boundary” of the classical moduli space of elliptic curves, which parameterizes those degenerations from lattices to pseudo-lattices, that are invisible to the usual algebro-geometric setting.

The cusp, *i.e.* the orbit of $\mathbb{P}^1(\mathbb{Q})$, corresponds to the degenerate case where the image in \mathbb{C} of the rank two free abelian group has rank one.

This gives another entry in the dictionary, regarding the moduli spaces:

$$\mathbb{H}/\mathrm{PSL}(2, \mathbb{Z}) \quad \longleftrightarrow \quad C(\mathbb{P}^1(\mathbb{R})) \rtimes \mathrm{PGL}(2, \mathbb{Z}).$$

In the correspondence of pseudo-lattices and noncommutative tori, the group of invertible morphisms of pseudo-lattices corresponds to isomorphisms of noncommutative tori realized by strong Morita equivalences. In this context a “morphism” is not given as a morphism of algebras but as a map of the category of modules, obtained by tensoring with a bimodule. The notion of Morita equivalences as morphisms fits into the more general context of correspondences for operator algebras as in [20] §V.B, as well as in the algebraic approach to noncommutative spaces of [86].

The category of noncommutative tori is defined by considering as morphisms the isomorphism classes of $(C^*$ -)bimodules that are range of

projections. The functor from noncommutative tori to pseudo-lattices (cf. [62] §3.3 and [63] §1.4) is then given on objects by

$$(3.67) \quad \mathcal{T}_\theta^2 \mapsto (K_0(\mathcal{A}_\theta), HC_0(\mathcal{A}_\theta), \tau : K_0(\mathcal{A}_\theta) \rightarrow HC_0(\mathcal{A}_\theta)).$$

Here \mathcal{A}_θ is the algebra of the noncommutative torus, $HC_0(\mathcal{A}_\theta) = \mathcal{A}_\theta/[\mathcal{A}_\theta, \mathcal{A}_\theta]$, with τ the universal trace, and the orientation is determined by the cone of positive elements in K_0 . On morphisms the functor is given by

$$(3.68) \quad \mathcal{M}_{\theta, \theta'} \mapsto ([\mathcal{E}] \mapsto [\mathcal{E} \otimes_{\mathcal{A}_\theta} \mathcal{M}_{\theta, \theta'}]),$$

where $\mathcal{M}_{\theta, \theta'}$ are the bimodules constructed by Connes in [15]. A crucial point in this definition is the fact that, for noncommutative tori, finite projective modules are classified by the value of a unique normalized trace (cf. [15] [85]).

The functor of (3.67) (3.68) is weaker than an equivalence of categories. For instance, it maps trivially all ring homomorphisms that act trivially on K_0 . However, this correspondence is sufficient to develop a theory of real multiplication for noncommutative tori parallel to the theory of complex multiplication for elliptic curves (cf. [62] [63]).

For lattices/elliptic curves, the typical situation is that $\text{End}(\Lambda) = \mathbb{Z}$, but there are exceptional lattices for which $\text{End}(\Lambda) \supsetneq \mathbb{Z}$. In this case, there exists a complex quadratic field \mathbb{K} such that Λ is isomorphic to a lattice in \mathbb{K} . More precisely, the endomorphism group is given by $\text{End}(\Lambda) = \mathbb{Z} + f\mathcal{O}$, where \mathcal{O} is the ring of integers of \mathbb{K} and the integer $f \geq 1$ is called the conductor. Such lattices are said to have complex multiplication. The elliptic curve $E_{\mathbb{K}}$ with $E_{\mathbb{K}}(\mathbb{C}) = \mathbb{C}/\mathcal{O}$ is endowed with a complex multiplication map, given on the universal cover by $x \mapsto ax$, $a \in \mathcal{O}$.

Similarly, there is a parallel situation for pseudo-lattices: $\text{End}(L) \supsetneq \mathbb{Z}$ happens when there exists a real quadratic field \mathbb{K} such that L is isomorphic to a pseudolattice contained in \mathbb{K} . In this case, one also has $\text{End}(L) = \mathbb{Z} + f\mathcal{O}$. Such pseudo-lattices are said to have *real multiplication*. The pseudo-lattices L_θ that have real multiplication correspond to values of $\theta \in \mathbb{R} \setminus \mathbb{Q}$ that are quadratic irrationalities. These are characterized by the having eventually periodic continued fraction expansion. The “real multiplication map” is given by tensoring with a bimodule: in the case of θ with periodic continued fraction expansion, there is an element $g \in \text{PGL}(2, \mathbb{Z})$ such that $g\theta = \theta$, to which we can associate an \mathcal{A}_θ - \mathcal{A}_θ bimodule \mathcal{E} .

An analog of isogenies for noncommutative tori is obtained by considering morphisms of pseudolattices $L_\theta \mapsto L_{n\theta}$ which correspond to a

Morita morphism given by \mathcal{A}_θ viewed as an $\mathcal{A}_{n\theta}$ - \mathcal{A}_θ bimodule, where $\mathcal{A}_{n\theta} \hookrightarrow \mathcal{A}_\theta$ by $U \mapsto U^n, V \mapsto V$.

By considering isogenies, one can enrich the dictionary between moduli space of elliptic curves and moduli space of Morita equivalent noncommutative tori. This leads one to consider the whole tower of modular curves parameterizing elliptic curves with level structure and the corresponding tower of noncommutative modular curves described in the previous chapter (*cf.* [70]),

$$(3.69) \quad \mathbb{H}/G \rightsquigarrow C(\mathbb{P}^1(\mathbb{R}) \times \mathbb{P}) \rtimes \Gamma,$$

for $\Gamma = \mathrm{PGL}(2, \mathbb{Z})$ (or $\mathrm{PSL}(2, \mathbb{Z})$) and $G \subset \Gamma$ a finite index subgroup, with $\mathbb{P} = G \backslash \Gamma$ the coset space.

In the problem of constructing the maximal abelian extension of complex quadratic fields, one method is based on evaluating at the torsion points of the elliptic curve $E_{\mathbb{K}}$ a power of the Weierstrass function. This means considering the corresponding values of a coordinate on the projective line $E_{\mathbb{K}}/\mathcal{O}^*$. The analogous object in the noncommutative setting, replacing this projective line, should be (*cf.* [63]) a crossed product of functions on \mathbb{K} by the $ax + b$ group with $a \in \mathcal{O}^*$ and $b \in \mathcal{O}$, for a real quadratic field \mathbb{K} .

A different method to construct abelian extensions of a complex quadratic field \mathbb{K} is via Stark numbers. Following the notation of [63], if $j : \Lambda \rightarrow V$ is an injective homomorphism of a free abelian group of rank two to a one-dimensional complex vector space, and $\lambda_0 \in \Lambda \otimes \mathbb{Q}$, then one can consider the zeta function

$$(3.70) \quad \zeta(\Lambda, \lambda_0, s) = \sum_{\lambda \in \Lambda} \frac{1}{|j(\lambda_0 + \lambda)|^{2s}}.$$

Stark proved (*cf.* [89]) that the numbers

$$(3.71) \quad S(\Lambda, \lambda_0) = \exp \zeta'(\Lambda, \lambda_0, 0)$$

are algebraic units generating certain abelian extensions of \mathbb{K} . The argument in this case is based on a direct computational tool (the Kronecker second limit formula) and upon reducing the problem to the theory of complex multiplication. There is no known independent argument for the Stark conjectures, while the analogous question is open for the case of real quadratic fields.

For a real quadratic field \mathbb{K} , instead of zeta functions of the form (3.70), the conjectural Stark units are obtained from zeta functions of the form (in the notation of [63])

$$(3.72) \quad \zeta(L, l_0, s) = \mathrm{sgn} \, l'_0 N(\mathfrak{a})^s \sum \frac{\mathrm{sgn}(l_0 + l)'}{|N(l_0 + l)|^s},$$

where $l \mapsto l'$ is the action of the nontrivial element in $Gal(\mathbb{K}/\mathbb{Q})$ and $N(l) = ll'$. The element $l_0 \in O$ is chosen so that the ideal $\mathfrak{a} = (L, l_0)$ and $(l_0)\mathfrak{a}^{-1}$ are coprime with $L\mathfrak{a}^{-1}$, and the summation over $l \in L$ in (3.72) is restricted by taking only one representative from each coset class $(l_0 + l)\epsilon$, for units ϵ satisfying $(l_0 + L)\epsilon = (l_0 + L)$, *i.e.* $\epsilon \equiv 1 \pmod{L\mathfrak{a}^{-1}}$. Then the Stark numbers are given as in (3.71) by (*cf.* [63])

$$(3.73) \quad S(L, l_0) = \exp \zeta'(L, l_0, 0).$$

In [63], Manin develops an approach to the computation of sums (3.72) based on a version of theta functions for pseudo-lattices, which are obtained by averaging theta constants of complex lattices along geodesics with ends at a pair of conjugate quadratic irrationalities θ, θ' in $\mathbb{R} \setminus \mathbb{Q}$.

This procedure fits into a general philosophy, according to which one can recast part of the arithmetic theory of modular curves in terms of the noncommutative boundary (3.69) by studying the limiting behavior when $\tau \rightarrow \theta \in \mathbb{R} \setminus \mathbb{Q}$ along geodesics, or some averaging along such geodesics. In general, some nontrivial result is obtained when approaching θ along a path that corresponds to a geodesic in the modular curve that spans a limiting cycle, which is the case precisely when the endpoint θ is a quadratic irrationality. An example of this type of behavior is the theory of “limiting modular symbols” developed in [70], [71].

5.2. Pseudolattices and the GL_2 -system. The noncommutative space (3.34) of the GL_2 -system also admits a compactification, now given by adding the boundary $\mathbb{P}^1(\mathbb{R})$ to \mathbb{H}^\pm , as in the noncommutative compactification of modular curves of [70],

$$(3.74) \quad \begin{aligned} \overline{Sh}^{(nc)}(GL_2, \mathbb{H}^\pm) &:= GL_2(\mathbb{Q}) \backslash (M_2(\mathbb{A}_f) \times \mathbb{P}^1(\mathbb{C})) \\ &= GL_2(\mathbb{Q}) \backslash M_2(\mathbb{A}) / \mathbb{C}^*, \end{aligned}$$

where $\mathbb{P}^1(\mathbb{C}) = \mathbb{H}^\pm \cup \mathbb{P}^1(\mathbb{R})$.

This corresponds to adding to the space of commensurability classes of 2-dimensional \mathbb{Q} -lattices the pseudolattices in the sense of [63], here considered together with a \mathbb{Q} -structure. It seems then that Manin’s real multiplication program may fit in with the boundary of the noncommutative space of the GL_2 -system. The crucial question in this respect becomes the construction of an arithmetic algebra associated to the noncommutative modular curves. The results illustrated in the previous chapter, regarding identities involving modular forms at the boundary of the classical modular curves and limiting modular symbols, as well as the still mysterious phenomenon of “quantum modular

forms” identified by Zagier, point to the fact that there should exist a rich class of objects replacing modular forms, when “pushed to the boundary”.

Regarding the role of modular forms, notice that, in the case of (3.74), we can again consider the dual system. This is a \mathbb{C}^* -bundle

$$(3.75) \quad \mathcal{L}_2 = \mathrm{GL}_2(\mathbb{Q}) \backslash M_2(\mathbb{A}).$$

On this dual space modular forms appear naturally instead of modular functions and the algebra of coordinates contains the modular Hecke algebra of Connes–Moscovici ([**33**], [**34**]) as arithmetic subalgebra.

Thus, the noncommutative geometry of the space of \mathbb{Q} -lattices modulo the equivalence relation of commensurability provides a setting that unifies several phenomena involving the interaction of noncommutative geometry and number theory. These include the Bost–Connes system, the noncommutative space underlying the construction of the spectral realization of the zeros of the Riemann zeta function in [**22**], the modular Hecke algebras of [**33**] [**34**], and the noncommutative modular curves of [**70**].

Noncommutative geometry at arithmetic infinity

This chapter is based on joint work of Katia Consani and the author ([36], [37], [38], [39], [40]) that proposes a model for the dual graph of the maximally degenerate fibers at the archimedean places of an arithmetic surface in terms of a noncommutative space (spectral triple) related to the action of a Schottky group on its limit set. This description of ∞ -adic geometry provides a compatible setting that combines Manin's result [66] on the Arakelov Green function for arithmetic surfaces in terms of hyperbolic geometry and for a cohomological construction of Consani [35] associated to the archimedean fibers of arithmetic varieties, related to Deninger's calculation of the local L -factors as regularized determinants (*cf.* [43], [44]).

1. Schottky uniformization

Topologically a compact Riemann surface X of genus g is obtained by gluing the sides of a $4g$ -gon. Correspondingly, the fundamental group has a presentation

$$\pi_1(X) = \langle a_1, \dots, a_g, b_1, \dots, b_g \mid \prod_i [a_i, b_i] = 1 \rangle,$$

where the generators a_i and b_i label the sides of the polygon.

In the genus $g = 1$ case, the parallelogram is the fundamental domain of the $\pi_1(X) \simeq \mathbb{Z}^2$ action on the plane \mathbb{C} , so that $X = \mathbb{C}/(\mathbb{Z} + \mathbb{Z}\tau)$ is an elliptic curve.

For genus at least $g \geq 2$, the hyperbolic plane \mathbb{H}^2 admits a tessellation by regular $4g$ -gons, and the action of the fundamental group by deck transformation is realized by the action of a subgroup $\pi_1(X) \simeq G \subset \mathrm{PSL}(2, \mathbb{R})$ by isometries of \mathbb{H}^2 . This endows the compact Riemann surface X with a hyperbolic metric and a Fuchsian uniformization

$$X = G \backslash \mathbb{H}^2.$$

Another, less well known, type of uniformization of compact Riemann surfaces is Schottky uniformization. We recall briefly some general facts on Schottky groups.

FIGURE 1. Limit set of a Schottky group

1.1. Schottky groups. A *Schottky group* of rank g is a discrete subgroup $\Gamma \subset \mathrm{PSL}(2, \mathbb{C})$, which is purely loxodromic and isomorphic to a free group of rank g . The group $\mathrm{PSL}(2, \mathbb{C})$ acts on $\mathbb{P}^1(\mathbb{C})$ by fractional linear transformations

$$\gamma : z \mapsto \frac{(az + b)}{(cz + d)}.$$

Thus, Γ also acts on $\mathbb{P}^1(\mathbb{C})$.

We denote by Λ_Γ the *limit set* of the action of Γ . This is the smallest non-empty closed Γ -invariant subset of $\mathbb{P}^1(\mathbb{C})$. This set can also be described as the closure of the set of the attractive and repelling fixed points $z^\pm(\gamma)$ of the loxodromic elements $\gamma \in \Gamma$. In the case $g = 1$ the limit set consists of two points, but for $g \geq 2$ the limit set is usually a fractal of some Hausdorff dimension $0 \leq \delta = \dim_H(\Lambda_\Gamma) < 2$ (*cf. e.g.* Figure 1¹).

We denote by Ω_Γ the *domain of discontinuity* of Γ , that is, the complement of Λ_Γ in $\mathbb{P}^1(\mathbb{C})$. The quotient

$$(4.1) \quad X(\mathbb{C}) = \Gamma \backslash \Omega_\Gamma$$

is a Riemann surface of genus g and the covering $\Omega_\Gamma \rightarrow X(\mathbb{C})$ is called a *Schottky uniformization* of $X(\mathbb{C})$.

¹Figures 1 and 3 are taken from “Indra’s pearls” by Mumford, Series, and Wright, [81]

FIGURE 2. Schottky uniformization for $g = 2$

Every compact Riemann surface $X(\mathbb{C})$ admits a Schottky uniformization.

Let $\{\gamma_i\}_{i=1}^g$ be a set of generators of the Schottky group Γ . We write $\gamma_{i+g} = \gamma_i^{-1}$. There are $2g$ Jordan curves γ_k on the sphere at infinity $\mathbb{P}^1(\mathbb{C})$, with pairwise disjoint interiors D_k , such that the elements γ_k are given by fractional linear transformations that map the interior of C_k to the exterior of C_j with $|k - j| = g$. The curves C_k give a *marking* of the Schottky group. The markings are circles in the case of *classical* Schottky groups. A fundamental domain for the action of a classical Schottky group Γ on $\mathbb{P}^1(\mathbb{C})$ is the region exterior to $2g$ -circles (*cf.* Figure 2).

1.2. Schottky and Fuchsian. Notice that, unlike Fuchsian uniformization, where the covering \mathbb{H}^2 is the universal cover, in the case of Schottky uniformization Ω_Γ is very far from being simply connected, in fact it is the complement of a Cantor set.

The relation between Fuchsian and Schottky uniformization is given by passing to the covering that corresponds to the normal subgroup $N\langle a_1, \dots, a_g \rangle$ of $\pi_1(X)$ generated by half the generators $\{a_1, \dots, a_g\}$,

$$\Gamma \simeq \pi_1(X)/N\langle a_1, \dots, a_g \rangle,$$

with a corresponding covering map

$$\begin{array}{ccc} \mathbb{H}^2 & \xrightarrow{J} & \Omega_\Gamma \\ & \searrow \pi_G & \swarrow \pi_\Gamma \\ & X & \end{array}$$

At the level of moduli, there is a corresponding map between Teichmüller space \mathcal{T}_g and Schottky space \mathcal{S}_g , which depends on $3g - 3$ complex moduli.

FIGURE 3. Classical and Fuchsian Schottky groups

1.3. Surface with boundary: simultaneous uniformization.

To better visualize geometrically the Schottky uniformization of a compact Riemann surface, we can relate it to a simultaneous uniformization of the upper and lower half planes that yields two Riemann surfaces with boundary, joined at the boundary.

A Schottky group that is specified by real parameters so that it lies in $\mathrm{PSL}(2, \mathbb{R})$ is called a *Fuchsian Schottky group* (cf. Figure 3). Viewed as a group of isometries of the hyperbolic plane \mathbb{H}^2 , or equivalently of the Poincaré disk, a Fuchsian Schottky group G produces a quotient $G \backslash \mathbb{H}^2$, which is topologically a Riemann surface with boundary.

A *quasi-circle* for Γ is a Jordan curve C in $\mathbb{P}^1(\mathbb{C})$ which is invariant under the action of Γ . In particular, such curve contains the limit set Λ_Γ . It was proved by Bowen that, if $X(\mathbb{C})$ is a Riemann surface of genus $g \geq 2$ with Schottky uniformization, then there exists always a quasi-circle for Γ .

We have then $\mathbb{P}^1(\mathbb{C}) \setminus C = \Omega_1 \cup \Omega_2$ and, for $\pi_\Gamma : \Omega_\Gamma \rightarrow X(\mathbb{C})$ the covering map,

$$\hat{C} = \pi_\Gamma(C \cap \Omega_\Gamma) \subset X(\mathbb{C})$$

is a set of curves on $X(\mathbb{C})$ that disconnect the Riemann surface in the union of two surfaces with boundary, uniformized respectively by Ω_1 and Ω_2 .

There exist conformal maps

$$\alpha_i : \Omega_i \xrightarrow{\cong} U_i, \quad U_1 \cup U_2 = \mathbb{P}^1(\mathbb{C}) \setminus \mathbb{P}^1(\mathbb{R})$$

with $U_i \simeq \mathbb{H}^2 =$ upper and lower half planes in $\mathbb{P}^1(\mathbb{C})$, and with

$$G_i := \{\alpha_i \gamma \alpha_i^{-1} : \gamma \in \tilde{\Gamma}\} \simeq \Gamma$$

Fuchsian Schottky groups $G_i \subset \mathrm{PSL}(2, \mathbb{R})$. Here $\tilde{\Gamma} \subset \mathrm{SL}(2, \mathbb{R})$ is the Γ -stabilizer of each of the two connected components in $\mathbb{P}^1(\mathbb{C}) \setminus C$.

FIGURE 4. Fuchsian Schottky groups: Riemann surfaces with boundary

The compact Riemann surface $X(\mathbb{C})$ is thus obtained as

$$X(\mathbb{C}) = X_1 \cup_{\partial X_1 = \hat{C} = \partial X_2} X_2,$$

with $X_i = U_i/G_i$ Riemann surfaces with boundary \hat{C} (cf. Figure 4).

In the case where $X(\mathbb{C})$ has a real structure $\iota : X \rightarrow X$, and the fixed point set $Fix(\iota) = X(\mathbb{R})$ of the involution ι is nonempty, we have in fact $\hat{C} = X(\mathbb{R})$, and the quasi-circle is given by $\mathbb{P}^1(\mathbb{R})$.

Notice that, in the case of a Fuchsian Schottky group, the Hausdorff dimension $\dim_H \Lambda_\Gamma$ of the limit set is in fact bounded above by 1, since Λ_Γ is contained in the rectifiable quasi-circle $\mathbb{P}^1(\mathbb{R})$.

1.4. Hyperbolic Handlebodies. The action of a rank g Schottky group $\Gamma \subset \text{PSL}(2, \mathbb{C})$ on $\mathbb{P}^1(\mathbb{C})$, by fractional linear transformations, extends to an action by isometries on real hyperbolic 3-space \mathbb{H}^3 . For a classical Schottky group, a fundamental domain in \mathbb{H}^3 is given by the region external to $2g$ half spheres over the circles $C_k \subset \mathbb{P}^1(\mathbb{C})$ (cf. Figure 5).

The quotient

$$(4.2) \quad \mathfrak{X}_\Gamma = \mathbb{H}^3/\Gamma$$

is topologically a handlebody of genus g filling the Riemann surface $X(\mathbb{C})$.

FIGURE 5. Genus two: fundamental domain in \mathbb{H}^3

Metrically, \mathfrak{X}_Γ is a real hyperbolic 3-manifold of infinite volume, having $X(\mathbb{C})$ as its conformal boundary at infinity $X(\mathbb{C}) = \partial\mathfrak{X}_\Gamma$.

We denote by $\overline{\mathfrak{X}}_\Gamma$ the compactification obtained by adding the conformal boundary at infinity,

$$(4.3) \quad \overline{\mathfrak{X}}_\Gamma = (\mathbb{H}^3 \cup \Omega_\Gamma)/\Gamma.$$

In the genus zero case, we just have the sphere $\mathbb{P}^1(\mathbb{C})$ as the conformal boundary at infinity of \mathbb{H}^3 , thought of as the unit ball in the Poincaré model.

In the genus one case we have a solid torus $\mathbb{H}^3/q^\mathbb{Z}$, for $q \in \mathbb{C}^*$ acting as

$$q(z, y) = (qz, |q|y)$$

in the upper half space model, with conformal boundary at infinity the Jacobi uniformized elliptic curve $\mathbb{C}^*/q^\mathbb{Z}$.

In this case, the limit set consists of the point $\{0, \infty\}$, the domain of discontinuity is \mathbb{C}^* and a fundamental domain is the annulus $\{|q| < |z| \leq 1\}$ (exterior of two circles).

The relation of Schottky uniformization to the usual Euclidean uniformization of complex tori $X = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ is given by $q = \exp(2\pi i\tau)$.

We shall return to the genus one case where we discuss a physical interpretation of Manin’s result on the Green function. To our purposes, however, the most interesting case is when the genus is $g \geq 2$. In this case, the limit set Λ_Γ is a Cantor set with an interesting dynamics of the action of Γ . It is the dynamics of the Schottky group on its limit set that generates an interesting noncommutative space.

FIGURE 6. Handlebody of genus 2: fundamental domains in \mathbb{H}^3

1.5. Geodesics in \mathfrak{X}_Γ . The hyperbolic handlebody \mathfrak{X}_Γ has infinite volume, but it contains a region of finite volume, which is a deformation retract of \mathfrak{X}_Γ . This is called the “convex core” of \mathfrak{X}_Γ and is obtained by taking the geodesic hull of the limit set Λ_Γ in \mathbb{H}^3 and then the quotient by Γ .

We identify different classes of infinite geodesics in \mathfrak{X}_Γ .

- *Closed geodesics:* since Γ is purely loxodromic, for all $\gamma \in \Gamma$ there exist two fixed points $\{z^\pm(\gamma)\} \in \mathbb{P}^1(\mathbb{C})$. The geodesics in $\mathbb{H}^3 \cup \mathbb{P}^1(\mathbb{C})$ with ends at two such points $\{z^\pm(\gamma)\}$, for some $\gamma \in \Gamma$, correspond to closed geodesics in the quotient \mathfrak{X}_Γ .
- *Bounded geodesics:* The images in \mathfrak{X}_Γ of geodesics in $\mathbb{H}^3 \cup \mathbb{P}^1(\mathbb{C})$ having both ends on the limit set Λ_Γ are geodesics that remain confined within the convex core of \mathfrak{X}_Γ .
- *Unbounded geodesics:* these are the geodesics in \mathfrak{X}_Γ that eventually wander off the convex core towards the conformal boundary $X(\mathbb{C})$ at infinity. They correspond to geodesics in $\mathbb{H}^3 \cup \mathbb{P}^1(\mathbb{C})$ with at least one end at a point of Ω_Γ .

In the genus one case, there is a unique primitive closed geodesic, namely the image in the quotient of the geodesic in \mathbb{H}^3 connecting 0 and ∞ . The bounded geodesics are those corresponding to geodesics in \mathbb{H}^3 originating at 0 or ∞ .

The most interesting case is that of genus $g \geq 2$, where the bounded geodesics form a complicated tangle inside \mathfrak{X}_Γ . Topologically, this is a generalized solenoid, namely it is locally the product of a line and a Cantor set.

2. Dynamics and noncommutative geometry

Since the uniformizing group Γ is a free group, there is a simple way of obtaining a coding of the bounded geodesics in \mathfrak{X}_Γ . The set of such geodesics can be identified with $\Lambda_\Gamma \times_\Gamma \Lambda_\Gamma$, by specifying the endpoints in $\mathbb{H}^3 \cup \mathbb{P}^1(\mathbb{C})$ modulo the action of Γ .

If $\{\gamma_i\}_{i=1}^g$ is a choice of generators of Γ and $\gamma_{i+g} = \gamma_i^{-1}$, $i = 1, \dots, g$, we can introduce a *subshift of finite type* (\mathcal{S}, T) where

$$(4.4) \quad \mathcal{S} = \{ \dots a_{-m} \dots a_{-1} a_0 a_1 \dots a_\ell \dots \mid a_i \in \{\gamma_i\}_{i=1}^{2g}, a_{i+1} \neq a_i^{-1}, \forall i \in \mathbb{Z} \}$$

is the set of doubly infinite words in the generators and their inverses, with the admissibility condition that no cancellations occur. The map T is the invertible shift

$$(4.5) \quad T(\dots a_{-m} \dots a_{-1} a_0 a_1 \dots a_\ell \dots) = \dots a_{-m+1} \dots a_0 a_1 a_2 \dots a_{\ell+1} \dots$$

Then we can pass from the discrete dynamical system (\mathcal{S}, T) to its suspension flow and obtain the mapping torus

$$(4.6) \quad \mathcal{S}_T := \mathcal{S} \times [0, 1] / (x, 0) \sim (Tx, 1).$$

Topologically this space is a solenoid, that is, a bundle over S^1 with fiber a Cantor set.

2.1. Homotopy quotient. The space \mathcal{S}_T of (4.6) has a natural interpretation in noncommutative geometry as the homotopy quotient in the sense of Baum–Connes [6] of the noncommutative space given by the C^* -algebra

$$(4.7) \quad C(\mathcal{S}) \rtimes_T \mathbb{Z}$$

describing the action of the shift (4.5) on the totally disconnected space (4.4). The noncommutative space (4.7) parameterizes bounded geodesics in the handlebody \mathfrak{X}_Γ .

The homotopy quotient is given by

$$\mathcal{S} \times_{\mathbb{Z}} \mathbb{R} = \mathcal{S}_T.$$

The K -theory of the C^* -algebra (4.7) can be computed via the Pimsner–Voiculescu six terms exact sequence,

$$\begin{array}{ccccc} K_1(A) & \longrightarrow & K_0(C(\mathcal{S})) & \xrightarrow{\delta=1-T} & K_0(C(\mathcal{S})) \\ & & \uparrow & & \downarrow \\ & & K_1(C(\mathcal{S})) & \longleftarrow & K_1(C(\mathcal{S})) & \longleftarrow & K_0(A) \end{array}$$

where $A = C(\mathcal{S}) \rtimes_T \mathbb{Z}$. Here, since the space \mathcal{S} is totally disconnected, we have $K_1(C(\mathcal{S})) = 0$ and $K_0(C(\mathcal{S})) = C(\mathcal{S}, \mathbb{Z})$ (locally constant integer valued functions). Thus the exact sequence becomes

$$(4.8) \quad 0 \rightarrow K_1(A) \rightarrow C(\mathcal{S}, \mathbb{Z}) \xrightarrow{\delta=1-T} C(\mathcal{S}, \mathbb{Z}) \rightarrow K_0(A) \rightarrow 0,$$

and we obtain $K_1(A) = \mathbb{Z} = \text{Ker}(\delta)$ and $K_0(A) = \text{Coker}(\delta)$. In dynamical systems language, these are respectively the *invariants* and *coinvariants* of the invertible shift T (cf. [10] [82]).

In terms of the homotopy quotient, one can describe this exact sequence more geometrically in terms of the Thom isomorphism and the μ -map

$$\mu : K^{*+1}(\mathcal{S}_T) \cong H^{*+1}(\mathcal{S}_T, \mathbb{Z}) \rightarrow K_*(C(\mathcal{S}) \rtimes_T \mathbb{Z}).$$

Thus, we obtain:

$$\begin{aligned} K_1(A) &\simeq H^0(\mathcal{S}_T) = \mathbb{Z} \\ K_0(A) &\simeq H^1(\mathcal{S}_T) \end{aligned}$$

The $H^1(\mathcal{S}_T)$ can be identified with the Čech cohomology group given by the homotopy classes $[\mathcal{S}_T, U(1)]$, by mapping $f \mapsto [\exp(2\pi i t f(x))]$, for $f \in C(\mathcal{S}, \mathbb{Z})/\delta$.

2.2. Filtration. The identification

$$H^1(\mathcal{S}_T, \mathbb{Z}) \cong K_0(C(\mathcal{S}) \rtimes_T \mathbb{Z})$$

of the cohomology of \mathcal{S}_T with the K_0 -group of the crossed product C^* -algebra for the action of T on \mathcal{S} endows $H^1(\mathcal{S}_T, \mathbb{Z})$ with a filtration.

THEOREM 2.1. *The first cohomology of \mathcal{S}_T is a direct limit*

$$H^1(\mathcal{S}_T) = \varinjlim_n F_n,$$

of free abelian groups $F_0 \hookrightarrow F_1 \hookrightarrow \dots \hookrightarrow F_n \hookrightarrow \dots$ of ranks $\text{rank } F_0 = 2g$ and $\text{rank } F_n = 2g(2g-1)^{n-1}(2g-2) + 1$, for $n \geq 1$.

In fact, by the Pimsner-Voiculescu six terms exact sequence, the group $K_0(C(\mathcal{S}) \rtimes_T \mathbb{Z})$ can be identified with the cokernel of the map $1 - T$ acting as $f \mapsto f - f \circ T$ on the \mathbb{Z} module $C(\mathcal{S}, \mathbb{Z}) \simeq K_0(C(\mathcal{S}))$.

Then the filtration is given by the submodules of functions depending only on the $a_0 \dots a_n$ coordinates in the doubly infinite words describing points in \mathcal{S} . Namely, one first shows that

$$H^1(\mathcal{S}_T, \mathbb{Z}) = C(\mathcal{S}, \mathbb{Z}) / \delta(C(\mathcal{S}, \mathbb{Z})) = \mathcal{P} / \delta\mathcal{P}$$

where \mathcal{P} denotes the \mathbb{Z} -module of locally constant \mathbb{Z} -valued functions that depend only on “future coordinates”. This can be identified with functions on the limit set Λ_Γ , since each point in Λ_Γ is described by an infinite (to the right) admissible sequence in the generators γ_i and their inverses. We have $\mathcal{P} \simeq C(\Lambda_\Gamma, \mathbb{Z})$.

The module \mathcal{P} clearly has a filtration by the submodules \mathcal{P}_n of functions of the first $n + 1$ coordinates. These have rank $\mathcal{P}_n = 2g(2g - 1)^n$.

We set $F_n := \mathcal{P}_n / \delta\mathcal{P}_{n-1}$. One can show that there are induced injections $F_n \hookrightarrow F_{n+1}$ and that

$$H^1(\mathcal{S}_T) = \varinjlim_n F_n.$$

Moreover, we have $\text{rank} F_n = \theta_n - \theta_{n-1} + 1$, where θ_n is the number of admissible words of length $n + 1$. All the \mathbb{Z} modules F_n and the quotients F_n / F_{n-1} are torsion free (cf. [82]).

2.3. Hilbert space and grading. It is convenient to consider the complex vector space

$$\mathcal{P}_{\mathbb{C}} = C(\Lambda_\Gamma, \mathbb{Z}) \otimes \mathbb{C}$$

and the corresponding exact sequence computing the cohomology with \mathbb{C} coefficients:

$$(4.9) \quad 0 \rightarrow \mathbb{C} \rightarrow \mathcal{P}_{\mathbb{C}} \xrightarrow{\delta} \mathcal{P}_{\mathbb{C}} \rightarrow H^1(\mathcal{S}_T, \mathbb{C}) \rightarrow 0$$

The complex vector space $\mathcal{P}_{\mathbb{C}}$ sits in the Hilbert space

$$\mathcal{P}_{\mathbb{C}} \subset \mathcal{L} = L^2(\Lambda_\Gamma, d\mu),$$

where μ is the Patterson–Sullivan measure on the limit set, satisfying

$$\gamma^* d\mu = |\gamma'|^{\dim_H(\Lambda_\Gamma)} d\mu,$$

with $\dim_H(\Lambda_\Gamma)$ the Hausdorff dimension.

This gives a Hilbert space \mathcal{L} , together with a filtration \mathcal{P}_n by finite dimensional subspaces. In such setting, it is natural to consider a

corresponding *grading operator*,

$$(4.10) \quad D = \sum_n n \hat{\Pi}_n,$$

where Π_n denotes the orthogonal projection onto \mathcal{P}_n and $\hat{\Pi}_n = \Pi_n - \Pi_{n-1}$.

2.4. Cuntz–Krieger algebra. There is a noncommutative space that encodes nicely the dynamics of the Schottky group Γ on its limit set Λ_Γ . Consider the $2g \times 2g$ matrix A that gives the admissibility condition for sequences in \mathcal{S} : this is the matrix with $\{0, 1\}$ entries satisfying $A_{ij} = 1$ for $|i - j| \neq g$ and $A_{ij} = 0$ otherwise.

The Cuntz–Krieger algebra \mathcal{O}_A associated to this matrix is the universal C^* -algebra generated by partial isometries S_i , $i = 1, \dots, 2g$, satisfying the relations

$$\sum_j S_j S_j^* = 1 \quad S_i^* S_i = \sum_j A_{ij} S_j S_j^*.$$

Recall that a partial isometry is an operator S satisfying $S = S S^* S$.

This algebra is related to the Schottky group by the following result.

PROPOSITION 2.2. *There is an isomorphism*

$$(4.11) \quad \mathcal{O}_A \cong C(\Lambda_\Gamma) \rtimes \Gamma.$$

Up to a stabilization (tensoring with compact operators), the algebra has another crossed product description as

$$(4.12) \quad \mathcal{O}_A \simeq \mathcal{F}_A \rtimes_T \mathbb{Z},$$

with \mathcal{F}_A an AF-algebra (a direct limit of finite dimensional C^* -algebras).

Consider the cochain complex of Hilbert spaces

$$0 \rightarrow \mathbb{C} \rightarrow \mathcal{L} \xrightarrow{\delta} \mathcal{L} \rightarrow \mathcal{H} \rightarrow 0$$

determined by the Pimsner–Voiculescu sequence (4.8).

PROPOSITION 2.3. *The C^* -algebra \mathcal{O}_A admits a faithful representation on the Hilbert space $\mathcal{L} = L^2(\Lambda_\Gamma, d\mu)$.*

This is obtained as follows.

For $d_H = \dim_H(\Lambda_\Gamma)$ the Hausdorff dimension, consider the operators

$$(4.13) \quad P_i f = \chi_{\gamma_i} f \quad T_i f = |(\gamma_i^{-1})'|^{d_H/2} f \circ \gamma_i^{-1},$$

where $\{\gamma_i\}$ are the generators of Γ and their inverses and

$$(4.14) \quad T_\gamma f = |\gamma'|^{d_H/2} f \circ \gamma.$$

Then the operators

$$(4.15) \quad S_i = \sum_j A_{ij} T_i^* P_j$$

are partial isometries on \mathcal{L} satisfying the Cuntz–Krieger relations for the matrix A of the subshift of finite type (4.4). This gives the representation of \mathcal{O}_A .

2.5. Spectral triple for Schottky groups. On the Hilbert space $\mathcal{H} = \mathcal{L} \oplus \mathcal{L}$ consider the diagonal action of the algebra \mathcal{O}_A and the Dirac operator \mathcal{D} defined as

$$(4.16) \quad \begin{aligned} \mathcal{D}|_{\mathcal{L} \oplus 0} &= \sum_n (n+1) (\hat{\Pi}_n \oplus 0) \\ \mathcal{D}|_{0 \oplus \mathcal{L}} &= -\sum_n n (0 \oplus \hat{\Pi}_n). \end{aligned}$$

The choice of the sign in (4.16) is not optimal from the point of view of the K -homology class. A better choice would be

$$F = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

This would require in turn a modification of $|D|$. A construction along these lines is being considered in joint work of the author with Alina Vdovina and Gunther Cornelissen. In our setting here, the reason for the choice (4.16) in [36] is the formula (4.91) relating \mathcal{D} to the “logarithm of Frobenius” at arithmetic infinity.

THEOREM 2.4. *For a Schottky group Γ with $\dim_H(\Lambda_\Gamma) < 1$, the data $(\mathcal{O}_A, \mathcal{H}, \mathcal{D})$, for $\mathcal{H} = \mathcal{L} \oplus \mathcal{L}$ with the diagonal action of \mathcal{O}_A through the representation (4.15) and the Dirac operator (4.16), define a non-finitely summable, θ -summable spectral triple.*

The key point of this result is the compatibility relation between the algebra and the Dirac operator, namely the fact that the commutators $[\mathcal{D}, a]$ are bounded operators, for all $a \in \mathcal{O}_A^{alg}$, the involutive subalgebra generated algebraically by the S_i subject to the Cuntz–Krieger relations.

This follows by an estimate on the norm of the commutators $\|[\mathcal{D}, S_i]\|$ and $\|[\mathcal{D}, S_i^*]\|$, in terms of the Poincaré series of the Schottky group ($d_H < 1$)

$$\sum_{\gamma \in \Gamma} |\gamma'|^s, \quad s = 1 > d_H,$$

where the Hausdorff dimension d_H is the exponent of convergence of the Poincaré series.

The dimension of the n -th eigenspace of \mathcal{D} is $2g(2g-1)^{n-1}(2g-2)$ for $n \geq 1$, $2g$ for $n = 0$ and $2g(2g-1)^{-n-1}(2g-2)$ for $n \leq -1$, so the spectral triple is not finitely summable, since $|\mathcal{D}|^z$ is not of trace class. It is θ summable, since the operator $\exp(-t\mathcal{D}^2)$ is of trace class, for all $t > 0$.

Using the description (4.12) of the noncommutative space as crossed product of an AF algebra by the action of the shift, $\mathcal{F}_A \rtimes_T \mathbb{Z}$, one may be able to find a 1-summable spectral triple. Here the dense subalgebra should not contain any of the group elements. In fact, by the result of [19], the group Γ is a free group, hence its growth is too fast to support finitely summable spectral triples on its group ring.

3. Arithmetic infinity: archimedean primes

An algebraic number field \mathbb{K} , which is an extension of \mathbb{Q} with $[\mathbb{K} : \mathbb{Q}] = n$ admits $n = r_1 + 2r_2$ embeddings

$$(4.17) \quad \alpha : \mathbb{K} \hookrightarrow \mathbb{C}.$$

These can be subdivided into r_1 real embeddings $\mathbb{K} \hookrightarrow \mathbb{R}$ and r_2 pairs of complex conjugate embeddings. The embeddings (4.17) are called the *archimedean primes* of the number field. The set of archimedean primes is often referred to as “arithmetic infinity”, a terminology borrowed from the case of the unique embedding of $\mathbb{Q} \hookrightarrow \mathbb{R}$, which is called the “infinite prime”.

A general strategy in arithmetic geometry is to adapt the tools of classical algebraic geometry to the arithmetic setting. In particular, over \mathbb{Q} the set of primes $\text{Spec}(\mathbb{Z})$ is the analog in arithmetic geometry of the affine line. It becomes clear then that some compactification is necessary, at least in order to have a well behaved form of intersection theory in arithmetic geometry. Namely, we need to pass from the “affine” $\text{Spec}(\mathbb{Z})$ to the projective case. The compactification is obtained by adding the infinite prime to the set of finite primes. A goal of arithmetic geometry then becomes developing a setting that treats the infinite prime and the finite primes of equal footing.

More generally, for a number field \mathbb{K} with $O_{\mathbb{K}}$ its ring of integers, the set of primes $\text{Spec}(O_{\mathbb{K}})$ is compactified by adding the set of “archimedean primes”

$$(4.18) \quad \overline{\text{Spec}(O_{\mathbb{K}})} = \text{Spec}(O_{\mathbb{K}}) \cup \{\alpha : \mathbb{K} \hookrightarrow \mathbb{C}\}.$$

3.1. Arithmetic surfaces. Let X be a smooth projective algebraic curve defined over \mathbb{Q} . Then, by clearing denominators one obtains an equation with \mathbb{Z} coefficients. This determines a scheme $X_{\mathbb{Z}}$

over $\text{Spec}(\mathbb{Z})$,

$$X_{\mathbb{Z}} \otimes_{\mathbb{Z}} \text{Spec}(\mathbb{Q}) = X,$$

where the closed fiber of $X_{\mathbb{Z}}$ at a prime $p \in \text{Spec}(\mathbb{Z})$ is the reduction $X \pmod p$. Thus, viewed as an arithmetic varieties, an algebraic curve becomes a 2-dimensional fibration over the affine line $\text{Spec}(\mathbb{Z})$.

One can also consider reductions of X (defined over \mathbb{Z}) modulo p^n for some prime $p \in \text{Spec}(\mathbb{Z})$. The limit as $n \rightarrow \infty$ defines a p -adic completion of $X_{\mathbb{Z}}$. This can be thought of as an “infinitesimal neighborhood” of the fiber at p .

The picture is more complicated at arithmetic infinity, since one does not have a suitable notion of “reduction mod ∞ ” available to define the closed fiber. On the other hand, one does have the analog of the p -adic completion at hand. This is given by the Riemann surface (smooth projective algebraic curve over \mathbb{C}) determined by the equation of the algebraic curve X over \mathbb{Q} , under the embedding of $\mathbb{Q} \subset \mathbb{C}$,

$$X(\mathbb{C}) = X \otimes_{\mathbb{Q}} \text{Spec}(\mathbb{C})$$

with the absolute value $|\cdot|$ at the infinite prime replacing the p -adic valuations.

Similarly, for \mathbb{K} a number field and $O_{\mathbb{K}}$ its ring of integers, a smooth proper algebraic curve X over \mathbb{K} determines a smooth minimal model $X_{O_{\mathbb{K}}}$, which defines an arithmetic surface $\mathcal{X}_{O_{\mathbb{K}}}$ over $\text{Spec}(O_{\mathbb{K}})$. The closed fiber X_{\wp} of $\mathcal{X}_{O_{\mathbb{K}}}$ over a prime $\wp \in O_{\mathbb{K}}$ is given by the reduction mod \wp .

When $\text{Spec}(O_{\mathbb{K}})$ is compactified by adding the archimedean primes, one also obtains n Riemann surfaces $X_{\alpha}(\mathbb{C})$, obtained from the equation defining X over \mathbb{K} under the embeddings $\alpha : \mathbb{K} \hookrightarrow \mathbb{C}$. Of these Riemann surfaces, r_1 carry a real involution.

Thus, the picture of an arithmetic surface over $\overline{\text{Spec}(O_{\mathbb{K}})}$ is as follows:

$$\begin{array}{ccccccc} X_{\wp} & \hookrightarrow & X_{\text{Spec}(O_{\mathbb{K}})} & \hookrightarrow & X_{\overline{\text{Spec}(O_{\mathbb{K}})}} & \longleftarrow & ??? \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ \wp & \hookrightarrow & \text{Spec}(O_{\mathbb{K}}) & \hookrightarrow & \overline{\text{Spec}(O_{\mathbb{K}})} & \longleftarrow & \alpha \end{array}$$

where we do not have an explicit geometric description of the closed fibers over the archimedean primes (Figure 7).

Formally, one can enlarge the group of divisors on the arithmetic surface by adding formal real linear combinations of irreducible “closed vertical fibers at infinity” $\sum_{\alpha} \lambda_{\alpha} F_{\alpha}$. Here the fibers F_{α} are only treated as formal symbols, and no geometric model of such fibers is provided.

FIGURE 7. Arithmetic surface over $\text{Spec}(\mathbb{Z})$

The remarkable fact is that Hermitian geometry on the Riemann surfaces $X_\alpha(\mathbb{C})$ is sufficient to specify the contribution of such divisors to intersection theory on the arithmetic surface, even without an explicit knowledge of the closed fiber.

The main idea of Arakelov geometry is that it is sufficient to work with the “infinitesimal neighborhood” $X_\alpha(\mathbb{C})$ of the fibers F_α , to have well defined intersection indices.

If one thinks, by analogy, to the case of the classical geometry of a degeneration of algebraic curves over a disk Δ , with a special fiber over 0 the analogous statement would be saying that the geometry of the special fiber is completely determined by the generic fiber. This is a very strong statement on the form of the degeneration: for instance blowing up points on the special fiber is not seen by just looking at the generic fiber. Investigating this analogy leads one to expect that the fiber at infinity should behave like the *totally degenerate* case. This is the case where one has maximal degeneration, where all the components of the closed fiber are \mathbb{P}^1 's and the geometry of the degeneration is completely encoded by the *dual graph*, which describes in a purely combinatorial way how these \mathbb{P}^1 's are joined. The dual graph has a vertex for each component of the closed fiber and an edge for each double point.

The local intersection multiplicities of two finite, horizontal, irreducible divisors D_1, D_2 on $X_{O_{\mathbb{K}}}$ is given by

$$[D_1, D_2] = [D_1, D_2]_{fin} + [D_1, D_2]_{inf}$$

where the first term counts the contribution from the finite places (*i.e.* what happens over $\text{Spec}(O_{\mathbb{K}})$) and the second term is the contribution of the archimedean primes, *i.e.* the part of the intersection that happens over arithmetic infinity.

While the first term is computed in algebro geometric terms, from the local equations for the divisors D_i at P , the second term is defined as a sum of values of Green functions g_α on the Riemann surfaces $X_\alpha(\mathbb{C})$,

$$[D_1, D_2]_{inf} = - \sum_{\alpha} \epsilon_{\alpha} \left(\sum_{\beta, \gamma} g_{\alpha}(P_{1, \beta}^{\alpha}, P_{2, \gamma}^{\alpha}) \right),$$

at points

$$\{P_{i, \beta}^{\alpha} \mid \beta = 1, \dots, [\mathbb{K}(D_i) : \mathbb{K}]\} \subset X_{\alpha}(\mathbb{C}),$$

for a finite extension $\mathbb{K}(D_i)$ of \mathbb{K} determined by D_i . Here $\epsilon_{\alpha} = 1$ for real embeddings and $= 2$ for complex embeddings.

For a detailed account of these notions of Arakelov geometry, one can refer to [41] [59].

Further evidence for the similarity between the archimedean and the totally degenerate fibers came from an explicit computation of the Green function at the archimedean places derived by Manin [66] in terms of a Schottky uniformization of the Riemann surface $X_{\alpha}(\mathbb{C})$. Such uniformization has an analog at a finite prime, in terms of p-adic Schottky groups, only in the totally degenerate case. Another source of evidence comes from a cohomological theory of the local factors at the archimedean primes, developed by Consani [35], which shows that the resulting description of the local factor as regularized determinant at the archimedean primes resembles mostly the case of the totally degenerate reduction at a finite prime.

We will present both results in the light of the noncommutative space $(\mathcal{O}_A, \mathcal{H}, \mathcal{D})$ introduced in the previous section. As showed by Consani and the author in [36] [37] [38] [39] the noncommutative geometry of this space is naturally related to both Manin’s result on the Arakelov Green function and the cohomological construction of Consani.

4. Arakelov geometry and hyperbolic geometry

In this section we give a detailed account of Manin’s result [66] on the relation between the Arakelov Green function on a Riemann surface $X(\mathbb{C})$ with Schottky uniformization and geodesics in the 3-dimensional hyperbolic handlebody \mathfrak{X}_{Γ} . Our exposition follows closely the seminal paper [66].

4.1. Arakelov Green function. Given a divisor $A = \sum_x m_x(x)$ with support $|A|$ on a smooth compact Riemann surface $X(\mathbb{C})$, and a choice of a positive real-analytic 2-form $d\mu$ on $X(\mathbb{C})$, the Green

function $g_{\mu,A} = g_A$ is a real analytic function on $X(\mathbb{C}) \setminus |A|$, uniquely determined by the following conditions:

- *Laplace equation:* g_A satisfies $\partial\bar{\partial} g_A = \pi i (\deg(A) d\mu - \delta_A)$, with δ_A the δ -current $\varphi \mapsto \sum_x m_x \varphi(x)$.
- *Singularities:* if z is a local coordinate in a neighborhood of x , then $g_A - m_x \log |z|$ is locally real analytic.
- *Normalization:* g_A satisfies $\int_X g_A d\mu = 0$.

If $B = \sum_y n_y(y)$ is another divisor, such that $|A| \cap |B| = \emptyset$, then the expression $g_\mu(A, B) := \sum_y n_y g_{\mu,A}(y)$ is symmetric and biadditive in A, B . Generally, such expression g_μ depends on μ , where the choice of μ is equivalent to the choice of a real analytic Riemannian metric on $X(\mathbb{C})$, compatible with the complex structure.

However, in the special case of degree zero divisors, $\deg A = \deg B = 0$, the $g_\mu(A, B) = g(A, B)$ are conformal invariants.

In the case on the Riemann sphere $\mathbb{P}^1(\mathbb{C})$, if w_A is a meromorphic function with $Div(w_A) = A$, we have

$$(4.19) \quad g(A, B) = \log \prod_{y \in |B|} |w_A(y)|^{n_y} = Re \int_{\gamma_B} \frac{dw_A}{w_A},$$

where γ_B is a 1-chain with boundary B .

In the case of degree zero divisors A, B on a Riemann surface of higher genus, the formula (4.19) can be generalized, replacing the logarithmic differential dw_A/w_A with a differential of the third kind (meromorphic differential with nonvanishing residues) ω_A with purely imaginary periods and residues m_x at x . This gives

$$(4.20) \quad g(A, B) = Re \int_{\gamma_B} \omega_A.$$

Thus, one can explicitly compute $g(A, B)$ from a basis of differentials of the third kind with purely imaginary periods.

4.2. Cross ratio and geodesics. The basic step leading to the result of Manin, expressing the Arakelov Green function in terms of geodesics in the hyperbolic handlebody \mathfrak{X}_Γ , is a very simple classical fact of hyperbolic geometry, namely the fact that the cross ratio of four points on $\mathbb{P}^1(\mathbb{C})$ can be expressed in terms of geodesics in the ‘interior’ \mathbb{H}^3 :

$$(4.21) \quad \log |\langle a, b, c, d \rangle| = -ordist(a * \{c, d\}, b * \{c, d\}).$$

Here, following [66], *ordist* denotes the oriented distance, and we use the notation $a * \{c, d\}$ to indicate the point on the geodesic $\{c, d\}$ in \mathbb{H}^3

FIGURE 8. Cross ratio and geodesic length

with endpoints $c, d \in \mathbb{P}^1(\mathbb{C})$, obtained as the intersection of $\{c, d\}$ with the unique geodesic from a that cuts $\{c, d\}$ at a right angle (Figure 8).

4.3. Differentials and Schottky uniformization. The next important step in Manin’s result [66] is to show that, if $X(\mathbb{C}) = \Gamma \backslash \Omega_\Gamma$ is a Riemann surface with a Schottky uniformization, then one obtains a basis of differentials of the third kind with purely imaginary periods, by taking suitable averages over the group Γ of expressions involving the cross ratio of points on $\mathbb{P}^1(\mathbb{C})$.

We denote by $C(|\gamma)$ a set of representatives of $\Gamma/(\gamma^\mathbb{Z})$, by $C(\rho|\gamma)$ a set of representatives for $(\rho^\mathbb{Z}) \backslash \Gamma/(\gamma^\mathbb{Z})$, and by $S(\gamma)$ the conjugacy class of γ in Γ .

Let w_A be a meromorphic function on $\mathbb{P}^1(\mathbb{C})$ with divisor $A = (a) - (b)$, such that the support $|A|$ is contained in the complement of an open neighborhood of Λ_Γ . We use the notation

$$(4.22) \quad \langle a, b, c, d \rangle := \frac{(a - b)(c - d)}{(a - d)(c - b)}$$

for the cross-ratio of points $a, b, c, d \in \mathbb{P}^1(\mathbb{C})$.

For a fixed choice of a base point $z_0 \in \Omega_\Gamma$, the series

$$(4.23) \quad \nu_{(a)-(b)} := \sum_{\gamma \in \Gamma} d \log \langle a, b, \gamma z, \gamma z_0 \rangle$$

gives the lift to Ω_Γ of a differential of the third kind on the Riemann surface $X(\mathbb{C})$, endowed with the choice of Schottky uniformization. These differentials have residues ± 1 at the images of a and b in $X(\mathbb{C})$, and they have vanishing a_k periods, where $\{a_k, b_k\}_{k=1\dots g}$ are the generators of the homology of $X(\mathbb{C})$.

Similarly, we obtain lifts of differentials of the first kind on $X(\mathbb{C})$, by considering the series

$$(4.24) \quad \omega_\gamma = \sum_{h \in C(l\gamma)} d \log \langle h z^+(\gamma), h z^-(\gamma), z, z_0 \rangle,$$

where we denote by $\{z^+(\gamma), z^-(\gamma)\} \subset \Lambda_\Gamma$ the pair of the attractive and repelling fixed points of $\gamma \in \Gamma$.

The series (4.23) and (4.24) converge absolutely on compact sets $K \subset \Omega_\Gamma$, whenever $\dim_H \Lambda_\Gamma < 1$. Moreover, they do not depend on the choice of the base point $z_0 \in \Omega_\Gamma$.

In particular, given a choice $\{\gamma_k\}_{k=1}^g$ of generators of the Schottky group Γ , we obtain by (4.24) a basis of holomorphic differentials ω_{γ_k} , that satisfy

$$(4.25) \quad \int_{a_k} \omega_{\gamma_\ell} = 2\pi\sqrt{-1} \delta_{k\ell}.$$

One can then use a linear combination of the holomorphic differentials ω_{γ_k} to correct the meromorphic differentials $\nu_{(a)-(b)}$ in such a way that the resulting meromorphic differentials have purely imaginary b_k -periods. Let $X_\ell(a, b)$ be coefficients such that the differentials of the third kind

$$(4.26) \quad \omega_{(a)-(b)} := \nu_{(a)-(b)} - \sum_{\ell} X_\ell(a, b) \omega_{g_\ell}$$

have purely imaginary b_k -periods. The coefficients $X_\ell(a, b)$ satisfy the system of equations

$$(4.27) \quad \sum_{\ell=1}^g X_\ell(a, b) \operatorname{Re} \tau_{k\ell} = \operatorname{Re} \int_{b_k} \nu_{(a)-(b)} = \sum_{h \in S(g_k)} \log |\langle a, b, z^+(h), z^-(h) \rangle|.$$

Thus, one obtains ([66], cf. also [93]) from (4.20) and (4.26) that the Arakelov Green function for $X(\mathbb{C})$ with Schottky uniformization can be computed as

$$(4.28) \quad \begin{aligned} g((a) - (b), (c) - (d)) &= \sum_{h \in \Gamma} \log |\langle a, b, hc, hd \rangle| \\ &- \sum_{\ell=1}^g X_\ell(a, b) \sum_{h \in S(g_\ell)} \log |\langle z^+(h), z^-(h), c, d \rangle|. \end{aligned}$$

Notice that this result seems to indicate that there is a choice of Schottky uniformization involved as additional data for Arakelov geometry at arithmetic infinity. However, as we remarked previously, at least in the case of archimedean primes that are real embeddings (as is the case of arithmetic infinity for \mathbb{Q}), the Schottky uniformization is determined by the real structure, by splitting $X(\mathbb{C})$ along the real locus $X(\mathbb{R})$, when the latter is nonempty.

4.4. Green function and geodesics. By combining the basic formula (4.21) with the formula (4.28) for the Green function on a Riemann surface with Schottky uniformization one can replace each term appearing in (4.28) with a corresponding term which computes the oriented geodesic length of a certain arc of geodesic in \mathfrak{X}_Γ :

$$(4.29) \quad g((a) - (b), (c) - (d)) = - \sum_{h \in \Gamma} \text{ordist}(a * \{hc, hd\}, b * \{hc, hd\}) \\ + \sum_{\ell=1}^g X_\ell(a, b) \sum_{h \in S(g_\ell)} \text{ordist}(z^+(h) * \{c, d\}, z^-(h) * \{c, d\}).$$

The coefficients $X_\ell(a, b)$ can also be expressed in terms of geodesics, using the equation (4.27).

5. Intermezzo: Quantum gravity and black holes

Anti de Sitter space AdS_{d+1} is a highly symmetric space–time, which satisfies Einstein’s equations with constant curvature $R < 0$. Physically it describes empty space with a negative cosmological constant. In order to avoid time–like closed geodesics, it is customary to pass to the universal cover $\tilde{\text{AdS}}_{d+1}$, whose boundary at infinity of the is a compactification of d –dimensional Minkowski space–time. When passing to Euclidean signature $\tilde{\text{AdS}}_{d+1}$ becomes the real hyperbolic space \mathbb{H}^{d+1} .

The 3 + 1 dimensional Anti de Sitter space is a well known example of space–time in general relativity. Topologically AdS_{3+1} is of the form $S^1 \times \mathbb{R}^3$, while metrically it is realized by the hyperboloid $-u^2 - v^2 + x^2 + y^2 + z^2 = 1$ in \mathbb{R}^5 , with the metric element $ds^2 = -du^2 - dv^2 + dx^2 + dy^2 + dz^2$. The universal cover is topologically \mathbb{R}^4 . In the context of quantum gravity, it is especially interesting to consider the case of the 2 + 1 dimensional Anti de Sitter space AdS_{2+1} and its Euclidean counterpart, the real 3-dimensional hyperbolic space \mathbb{H}^3 .

The holography principle postulates the existence of an explicit correspondence between gravity on a bulk space which is asymptotically $\tilde{\text{AdS}}_{d+1}$ (*e.g.* a space obtained as a global quotient of $\tilde{\text{AdS}}_{d+1}$ by a discrete group of isometries) and field theory on its conformal boundary at infinity.

The relation (4.21), that identifies the Green function

$$g((a) - (b), (c) - (d))$$

on $\mathbb{P}^1(\mathbb{C})$ with the oriented length of a geodesic arc in \mathbb{H}^3 , can be thought of as an instance of this holography principle, when we interpret one side as geodesic propagator on the bulk space in a semi-classical approximation, and the other side (the Green function) as the two point correlation function of the boundary field theory. Notice that, because of the prescribed behavior of the Green function at the singularities given by the points of the divisor, our “four-points” $g((a) - (b), (c) - (d))$, when $a \rightarrow c$ and $b \rightarrow d$, gives the two point correlator with a logarithmic divergence which is intrinsic and does not depend on a choice of cut-off functions (unlike the regularization often used in the physics literature).

In [69] we showed that the relation (4.29) between Arakelov Green functions and configurations of geodesics in the hyperbolic handlebody, proved by Manin in [66], provides in fact precisely the correspondence prescribed by the holography principle, for a class of $2 + 1$ dimensional space-times known as Euclidean Krasnov black holes. These include the Bañados–Teitelboim–Zanelli black holes: an important class of space-times in the context of $(2 + 1)$ -dimensional quantum gravity.

5.1. Bañados–Teitelboim–Zanelli black hole. We consider the case of a hyperbolic handlebody of genus one (a solid torus), with conformal boundary at infinity given by an elliptic curve.

Recall that we can describe elliptic curves via the Jacobi uniformization. (We have already encountered it in the previous lectures, in the context of non-commutative elliptic curves.) Let $X_q(\mathbb{C}) = \mathbb{C}^*/q^{\mathbb{Z}}$ be such description of an elliptic curve, where q is a hyperbolic element of $\mathrm{PSL}(2, \mathbb{C})$ with fixed points $\{0, \infty\}$ on the sphere at infinity $\mathbb{P}^1(\mathbb{C})$ of \mathbb{H}^3 , that is, $q \in \mathbb{C}^*$ with $|q| < 1$. The action of q on $\mathbb{P}^1(\mathbb{C})$ extends to an action on $\bar{\mathbb{H}}^3 = \mathbb{H}^3 \cup \mathbb{P}^1(\mathbb{C})$ by

$$q : (z, y) \mapsto (qz, |q|y).$$

It is easy to see that the quotient by this action

$$(4.30) \quad \mathfrak{X}_q = \mathbb{H}^3/q^{\mathbb{Z}}$$

is topologically a solid torus, compactified at infinity by the conformal boundary $X_q(\mathbb{C})$.

The space \mathfrak{X}_q is well known in the physics literature as the Euclidean Bañados–Teitelboim–Zanelli black hole, where the parameter $q \in \mathbb{C}^*$ is

FIGURE 9. Minkowskian BTZ black hole

written in the form

$$q = \exp\left(\frac{2\pi(i|r_-| - r_+)}{\ell}\right),$$

with

$$r_{\pm}^2 = \frac{1}{2} \left(M\ell \pm \sqrt{M^2\ell^2 + J} \right).$$

Here M and J are the mass and angular momentum of the rotating black hole, and $-1/\ell^2$ is the cosmological constant. The corresponding black hole in Minkowskian signature is illustrated in Figure 9².

In the case of the elliptic curve $X_q(\mathbb{C}) = \mathbb{C}^*/q^{\mathbb{Z}}$, a formula of Alvarez-Gaume, Moore, and Vafa gives the operator product expansion of the path integral for bosonic field theory as

$$g(z, 1) = \log \left(|q|^{B_2(\log |z|/\log |q|)/2} |1 - z| \prod_{n=1}^{\infty} |1 - q^n z| |1 - q^n z^{-1}| \right).$$

This is in fact the Arakelov Green function on $X_q(\mathbb{C})$. In terms of geodesics in the Euclidean BTZ black hole this becomes (*cf.* [66])

$$g(z, 1) = -\frac{1}{2}\ell(\gamma_0) B_2 \left(\frac{\ell_{\gamma_0}(\bar{z}, \bar{1})}{\ell(\gamma_0)} \right) + \sum_{n \geq 0} \ell_{\gamma_1}(\bar{0}, \bar{z}_n) + \sum_{n \geq 1} \ell_{\gamma_1}(\bar{0}, \bar{z}_n).$$

²Figure 9 is taken from [2].

FIGURE 10. Geodesics in Euclidean BTZ black holes

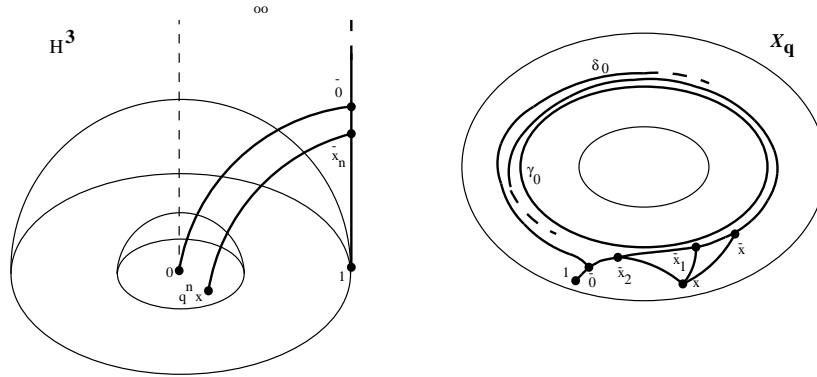

FIGURE 11. Geodesics in Euclidean BTZ black holes

Here we are using the notation $\bar{x} = x * \{0, \infty\}$; $\bar{z}_n = q^n z * \{1, \infty\}$, $\tilde{z}_n = q^n z^{-1} * \{1, \infty\}$ as in [66], as illustrated in Figure 10 and 11. These terms describe gravitational properties of the Euclidean BTZ black hole. For instance, $\ell(\gamma_0)$ measures the black hole entropy. The whole expression is a combination of geodesic propagators.

5.2. Krasnov black holes. The problem of computing the bosonic field propagator on an algebraic curve $X_{\mathbb{C}}$ can be solved by providing differentials of the third kind with purely imaginary periods

$$\omega_{(a)-(b)} := \nu_{(a)-(b)} - \sum_l X_l(a, b)\omega_{g_l},$$

hence it can be related directly to the problem of computing the Arakelov Green function.

Differentials as above then determine all the higher correlation functions

$$G(z_1, \dots, z_m; w_1, \dots, w_\ell) = \sum_{j=1}^m \sum_{i=1}^{\ell} q_i \langle \phi(z_i, \bar{z}_i) \phi(w_j, \bar{w}_j) \rangle q'_j,$$

for q_i a system of charges at positions z_i interacting with q'_j charges at positions w_j , from the basic two point correlator $G_\mu(a-b, z)$ given by the Green function expressed in terms of the differentials $\omega_{(a)-(b)}(z)$. When we use a Schottky uniformization, we obtain the differentials $\omega_{(a)-(b)}$ as in (4.26).

The bulk space corresponding to the conformal boundary $X(\mathbb{C})$ is given by the hyperbolic handlebody \mathfrak{X}_Γ . As in the case of the BTZ black hole, it is possible to interpret these real hyperbolic 3-manifolds as *analytic continuations* to Euclidean signature of Minkowskian black holes that are global quotients of AdS_{2+1} . This is not just the effect of the usual rotation from Minkowskian to Euclidean signature, but a more refined form of “analytic continuation” which is adapted to the action of the Schottky group, and which was introduced by Kirill Krasnov [53] [54] in order to deal with this class of space-times.

The formula (4.29) then gives the explicit bulk/boundary correspondence of the holography principle for this class of space-times: each term in the Bosonic field propagator for $X_{\mathbb{C}}$ is expressed in terms of geodesics in the Euclidean Krasnov black hole $\mathfrak{X}_\Gamma = \mathbb{H}^3/\Gamma$.

6. Dual graph and noncommutative geometry

Manin’s result on the Arakelov Green function and hyperbolic geometry suggests a geometric model for the dual graph of the mysterious fiber at arithmetic infinity.

In fact, the result discussed above on the Green function has an analog, due to Drinfel’d and Manin [46] in the case of a finite prime with a totally split fiber. This is the case where the p -adic completion admits a Schottky uniformization by a p -adic Schottky group.

6.1. Schottky–Mumford curves. If K is a given finite extension of \mathbb{Q}_p , we denote by $\mathcal{O} \subset K$ its ring of integers, by $\mathfrak{m} \subset \mathcal{O}$ the maximal ideal, and by k the residue field $k = \mathcal{O}/\mathfrak{m}$. This is a finite field of cardinality $q = \text{card}(\mathcal{O}/\mathfrak{m})$.

It is well known that a curve X over a finite extension K of \mathbb{Q}_p , which is k -split degenerate, for k the residue field, admits a p -adic uniformization by a p -adic Schottky group Γ acting on the Bruhat-Tits tree Δ_K .

FIGURE 12. Mumford curve of genus one: Jacobi-Tate uniformized elliptic curve

The Bruhat-Tits tree is obtained by considering free \mathcal{O} -modules of rank 2, with the equivalence relation that $M_1 \sim M_2$ iff $\exists \lambda \in K^*$, such that $M_1 = \lambda M_2$. The vertices of the tree consist of these equivalence classes. A distance is introduced on this set by prescribing that if $\{M_1\}, \{M_2\} \in \Delta_K^0$, with $M_1 \supset M_2$, then

$$M_1/M_2 \simeq \mathcal{O}/\mathfrak{m}^l \oplus \mathcal{O}/\mathfrak{m}^k, \quad l, k \in \mathbb{N}$$

and we set the distance to be $d(\{M_1\}, \{M_2\}) = |l - k|$. We form the tree Δ_K , by adding an edge between any two pairs of vertices with $d(\{M_1\}, \{M_2\}) = 1$. This gives a connected, locally finite tree with $q + 1$ edges departing from each vertex. The group $\text{PGL}(2, K)$ acts transitively (on the left) by isometries.

The Bruhat-Tits tree Δ_K is the analog of the 3-dimensional real hyperbolic space \mathbb{H}^3 at the infinite primes. The set of ends of Δ_K is identified with $\mathbb{P}^1(K)$, just as we have $\mathbb{P}^1(\mathbb{C}) = \partial\mathbb{H}^3$ in the case at infinity.

A p -adic Schottky group Γ is a discrete subgroup of $\text{PGL}(2, K)$ which consists of hyperbolic elements (the eigenvalues of in K have different valuation), and which is isomorphic to a free group in g generators. We still denote by $\Lambda_\Gamma \subset \mathbb{P}^1(K)$ the limit set, that is, the closure of the set of points in $\mathbb{P}^1(K)$ that are fixed points of some

FIGURE 13. Genus two: special fibers and dual graphs

$\gamma \in \Gamma \setminus \{1\}$. As in the case at infinity, we have $\text{card}(\Lambda_\Gamma) < \infty$ if and only if $\Gamma = (\gamma)^\mathbb{Z}$, for some $\gamma \in \Gamma$ (the genus one case). We denote by $\Omega_\Gamma = \Omega_\Gamma(K)$ the complement $\Omega_\Gamma = \mathbb{P}^1(K) \setminus \Lambda_\Gamma$, that is, the domain of discontinuity of Γ .

In the case of genus $g \geq 2$ the quotient

$$X_\Gamma := \Omega_\Gamma/\Gamma$$

is a Schottky–Mumford curve, with p -adic Schottky uniformization. The case of genus one gives the Jacobi-Tate uniformization of the elliptic curve (Figure 12).

A path in Δ_K , infinite in both directions and with no back-tracking, is called an *axis* of Δ_K . Any two points $z_1, z_2 \in \mathbb{P}^1(K)$ uniquely define their connecting axis with endpoints at z_1 and z_2 in $\partial\Delta_K$. The unique axis of Δ_K whose ends are the fixed points of an hyperbolic element γ is called the axis of γ . The element γ acts on its axis as a translation. We denote by $\Delta'_\Gamma \subset \Delta_K$ the smallest subtree containing the axes of all elements of Γ .

This subtree is Γ -invariant, with set of ends Λ_Γ . The quotient Δ'_Γ/Γ is a *finite graph*, which is the dual graph of the closed fiber of the *minimal smooth model* over \mathcal{O} (k -split degenerate semi-stable curve) of X_Γ . Figure 13 shows the special fiber and the corresponding dual graph for all the possible cases of maximal degenerations special for genus two. Figure 14 shows the corresponding trees Δ'_Γ .

FIGURE 14. Genus two: trees and dual graphs

For each $n \geq 0$, we can also consider a subgraph $\Delta_{K,n}$ of the Bruhat-Tits tree Δ_K defined by setting

$$\Delta_{K,n}^0 := \{v \in \Delta_K^0 : d(v, \Delta'_\Gamma) \leq n\},$$

where d is the distance on Δ_K and $d(v, \Delta'_\Gamma) := \inf\{d(v, \tilde{v}) : \tilde{v} \in (\Delta'_\Gamma)^0\}$, and

$$\Delta_{K,n}^1 := \{w \in \Delta_K^1 : s(w), r(w) \in \Delta_{K,n}^0\}.$$

In particular, we have $\Delta_{K,0} = \Delta'_\Gamma$.

For all $n \in \mathbb{N}$, the graph $\Delta_{K,n}$ is invariant under the action of the Schottky group Γ on Δ , and the finite graph $\Delta_{K,n}/\Gamma$ gives the dual graph of the reduction $X_K \otimes \mathcal{O}/\mathfrak{m}^{n+1}$.

For a more detailed account of Schottky–Mumford curves see [80] and [67].

6.2. Model of the dual graph. The dictionary between the case of Mumford curves and the case at arithmetic infinity is then summarized as follows:

Bruhat–Tits Δ_K	Hyperbolic 3-space \mathbb{H}^3
$\mathbb{P}^1(K) = \partial\Delta_K$	$\mathbb{P}^1(\mathbb{C}) = \partial\mathbb{H}^3$
Schottky $\Gamma \subset \mathrm{PGL}(2, K)$	Schottky $\Gamma \subset \mathrm{PSL}(2, \mathbb{C})$
paths in Δ_K	geodesics in \mathbb{H}^3
Mumford curve Ω_Γ/Γ	Riemann surface Ω_Γ/Γ
tree Δ'_Γ	convex core in \mathbb{H}^3
graph Δ_K/Γ	handlebody \mathfrak{X}_Γ
dual graph Δ'_Γ/Γ	bounded geodesics in \mathfrak{X}_Γ

Since we can identify bounded geodesics in \mathfrak{X}_Γ with infinite geodesics in \mathbb{H}^3 with endpoints on $\Lambda_\Gamma \subset \mathbb{P}^1(\mathbb{C})$, modulo the action of Γ , these are parameterized by the complement of the diagonal in $\Lambda_\Gamma \times_\Gamma \Lambda_\Gamma$. This quotient is identified with the quotient of the totally disconnected space \mathcal{S} of (4.4) by the action of the invertible shift T of (4.5). Thus we obtain the following model for the dual graph of the fiber at infinity:

- The solenoid \mathcal{S}_T of (4.6) is a geometric model of the dual graph of the fiber at infinity of an arithmetic surface.
- The noncommutative space \mathcal{O}_A , representing the algebra of coordinates on the quotient Λ_Γ/Γ , corresponds to the set of “vertices of the dual graph” (set of components of the fiber at infinity), while the noncommutative space (4.7), corresponding to the quotient $\Lambda_\Gamma \times_\Gamma \Lambda_\Gamma$ gives the set of “edges of the dual graph”.

Moreover, using noncommutative geometry, one can also give a notion of “reduction mod ∞ ” analogous to the reduction maps mod p^m defined by the graphs $\Delta_{K,n}$ in the case of Mumford curves.

In fact, the reduction map corresponds to the paths connecting ends of the graph $\Delta_{K,n}/\Gamma$ to corresponding vertices of the graph $\Delta'_\Gamma/\Gamma = \Delta_{K,0}/\Gamma$. The analog at arithmetic infinity consists then of geodesics in \mathfrak{X}_Γ which are the image of geodesics in \mathbb{H}^3 starting at some point $x_0 \in \mathbb{H}^3 \cup \Omega_\Gamma$ and having the other end at a point of Λ_Γ . These are parameterized by the set

$$\Lambda_\Gamma \times_\Gamma (\mathbb{H}^3 \cup \Omega_\Gamma).$$

Thus, in terms of noncommutative geometry, the reduction mod ∞ corresponds to a compactification of the homotopy quotient

$$\Lambda_\Gamma \times_\Gamma \mathbb{H}^3 = \Lambda_\Gamma \times_\Gamma \underline{E}\Gamma$$

where

$$\underline{B}\Gamma = \mathbb{H}^3/\Gamma = \mathfrak{X}_\Gamma.$$

Thus, we can view Λ_Γ/Γ as the quotient of a foliation on the homotopy quotient with contractible leaves \mathbb{H}^3 . The reduction mod ∞ is

then given by the μ -map

$$\mu : K^{*+1}(\Lambda_\Gamma \times_\Gamma \mathbb{H}^3) \rightarrow K_*(C(\Lambda_\Gamma) \rtimes \Gamma).$$

This shows that the noncommutative space $(\mathcal{O}_A, \mathcal{H}, \mathcal{D})$ is closely related to the geometry of the fiber at arithmetic infinity of an algebraic variety. One can ask then what arithmetic information is captured by the Dirac operator \mathcal{D} of this spectral triples. We'll see in the next section that (as proved in [36]), the Dirac operator gives another important arithmetic invariant, namely the local L -factor at the archimedean prime.

7. Arithmetic varieties and L -factors

An important invariant of arithmetic varieties is the L -function. This is written as a product of contributions from the finite primes and the archimedean primes,

$$(4.31) \quad \prod_{\wp \in \overline{\text{Spec } \mathcal{O}_\mathbb{K}}} L_\wp(H^m(X), s).$$

We do not plan to give a detailed account on the subject, but we refer the interested reader to [87]. Here we only try to convey some basic ideas.

The reason why one needs to consider also the contribution of the archimedean primes can be seen in the case of the “affine line” $\text{Spec}(\mathbb{Z})$, where one has the Riemann zeta function, which is written as the Euler product

$$(4.32) \quad \zeta(s) = \prod_p (1 - p^{-s})^{-1}.$$

However, to have a nice functional equation, one needs to consider the product

$$(4.33) \quad \zeta(s) \Gamma(s/2) \pi^{-s/2},$$

which includes a contribution of the archimedean prime, expressed in terms of the Gamma function

$$(4.34) \quad \Gamma(s) = \int_0^\infty e^{-t} t^{s-1} dt.$$

An analogy with ordinary geometry suggests to think of the functional equation as a sort of “Poincaré duality”, which holds for a compact manifold, hence the need to “compactify” arithmetic varieties by adding the archimedean primes and the corresponding archimedean fibers.

When one looks at an arithmetic variety over a finite prime $\wp \in \text{Spec}(O_{\mathbb{K}})$, the fact that the reduction lives over a residue field of positive characteristic implies that there is a special operator, the *geometric Frobenius* Fr_{\wp}^* , acting on a suitable cohomology theory (étale cohomology), induced by the Frobenius automorphism ϕ_{\wp} of $\text{Gal}(\bar{\mathbb{F}}_p/\mathbb{F}_p)$.

The local L -factors of (4.31) at finite primes encodes the action of the geometric Frobenius in the form [87]

$$(4.35) \quad L_{\wp}(H^m(X), s) = \det(1 - Fr_{\wp}^* N(\wp)^{-s} | H^m(\bar{X}, \mathbb{Q}_{\ell})^{I_{\wp}})^{-1}.$$

Here we are considering the action of the geometric Frobenius Fr_{\wp}^* on the *inertia invariants* $H^m(\bar{X}, \mathbb{Q}_{\ell})^{I_{\wp}}$ of the étale cohomology. An introduction to étale cohomology and a precise definition of these arithmetic structures is beyond the purpose of these notes. In fact, our primary concern will only be the contribution of the archimedean primes to (4.31), where the construction will be based on ordinary de Rham cohomology. Thus, we only give a quick and somewhat heuristic explanation of (4.35). We refer to [87] [91] for a detailed and rigorous account and for the precise hypothesis under which the following holds.

For X a smooth projective algebraic variety (in any dimension) defined over \mathbb{Q} , the notation \bar{X} denotes

$$\bar{X} := X \otimes \text{Spec}(\bar{\mathbb{Q}}),$$

where $\bar{\mathbb{Q}}$ is an algebraic closure. For ℓ a prime, the cohomology $H^*(\bar{X}, \mathbb{Q}_{\ell})$ is a finite dim \mathbb{Q}_{ℓ} -vector space satisfying

$$(4.36) \quad H^i(X(\mathbb{C}), \mathbb{C}) \simeq H^i(\bar{X}, \mathbb{Q}_{\ell}) \otimes \mathbb{C}.$$

The absolute Galois group $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ acts on $H^*(\bar{X}, \mathbb{Q}_{\ell})$.

Similarly, we can consider $H^*(\bar{X}, \mathbb{Q}_{\ell})$ for X defined over a number field \mathbb{K} . For $\wp \in \text{Spec}(O_{\mathbb{K}})$ and ℓ a prime such that $(\ell, q) = 1$, where q is the cardinality of the residue field at \wp , the inertia invariants

$$(4.37) \quad H^*(\bar{X}, \mathbb{Q}_{\ell})^{I_{\wp}} \subset H^*(\bar{X}, \mathbb{Q}_{\ell})$$

are the part of the ℓ -adic cohomology where the inertia group at \wp acts trivially. The latter is defined as

$$(4.38) \quad I_{\wp} = \text{Ker}(D_{\wp} \rightarrow \text{Gal}(\bar{\mathbb{F}}_p/\mathbb{F}_p)),$$

with $D_{\wp} = \{\sigma \in \text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \mid \sigma(\wp) = \wp\}$. The Frobenius automorphism of $\text{Gal}(\bar{\mathbb{F}}_p/\mathbb{F}_p)$ lifts to $\phi_{\wp} \in D_{\wp}/I_{\wp}$ and induces the geometric Frobenius $F_{\wp}^* := (\phi_{\wp}^{-1})^*$ acting on $H^*(\bar{X}, \mathbb{Q}_{\ell})^{I_{\wp}}$. We use the notation N in (4.35) for the norm map. Thus, we can write the local L -factor (4.35)

equivalently as

$$(4.39) \quad L_\varphi(H^m(X), s) = \prod_{\lambda \in \text{Spec}(Fr_\varphi^*)} (1 - \lambda q^{-s})^{-\dim H^m(X)_\lambda^{I_\varphi}},$$

where $H^m(X)_\lambda^{I_\varphi}$ is the eigenspace of the Frobenius with eigenvalue λ .

For our purposes, what is most important to retain from the discussion above is that the local L -factor (4.35) depends upon the data

$$(4.40) \quad (H^*(\bar{X}, \mathbb{Q}_\ell)^{I_\varphi}, Fr_\varphi^*)$$

of a vector space, which has a cohomological interpretation, together with a linear operator.

7.1. Archimedean L -factors. Since étale cohomology satisfies the compatibility (4.36), if we again resort to the general philosophy, according to which we can work with the smooth complex manifold $X(\mathbb{C})$ and gain information on the “closed fiber” at arithmetic infinity, we are lead to expect that the contribution of the archimedean primes to the L -function may be expressed in terms of the cohomology $H^*(X(\mathbb{C}), \mathbb{C})$, or equivalently in terms of de Rham cohomology.

In fact, Serre showed ([87]) that the expected contribution of the archimedean primes depends upon the Hodge structure

$$(4.41) \quad H^m(X(\mathbb{C})) = \bigoplus_{p+q=m} H^{p,q}(X(\mathbb{C}))$$

and is again expressed in terms of Gamma functions, as in the case of (4.33). Namely, one has a product of Gamma functions according to the Hodge numbers $h^{p,q}$,

$$(4.42) \quad L(H^*, s) = \begin{cases} \prod_{p,q} \Gamma_{\mathbb{C}}(s - \min(p, q))^{h^{p,q}} \\ \prod_{p < q} \Gamma_{\mathbb{C}}(s - p)^{h^{p,q}} \prod_p \Gamma_{\mathbb{R}}(s - p)^{h^{p,+}} \Gamma_{\mathbb{R}}(s - p + 1)^{h^{p,-}} \end{cases}$$

where the two cases correspond, respectively, to the complex and the real embeddings. Here $h^{p,\pm}$ is the dimension of the $\pm(-1)^p$ -eigenspace of the involution on $H^{p,p}$ induced by the real structure and

$$(4.43) \quad \Gamma_{\mathbb{C}}(s) := (2\pi)^{-s} \Gamma(s), \quad \Gamma_{\mathbb{R}}(s) := 2^{-1/2} \pi^{-s/2} \Gamma(s/2).$$

One of the general ideas in arithmetic geometry is that one should always seek a unified picture of what happens at the finite and at the infinite primes. In particular, there should be a suitable reformulation of the local factors (4.35) and (4.42) where both formulae can be expressed in the same way.

Seeking a unified description of local L -factors at finite and infinite primes, Deninger in [43], [44], [45] expressed both (4.35) and (4.42) as infinite determinants.

Recall that the Ray-Singer determinant of an operator T with pure point spectrum with finite multiplicities $\{m_\lambda\}_{\lambda \in \text{Spec}(T)}$ is defined as

$$(4.44) \quad \det_\infty(s - T) := \exp\left(-\frac{d}{dz}\zeta_T(s, z)|_{z=0}\right)$$

where the zeta function of T is defined as

$$(4.45) \quad \zeta_T(s, z) = \sum_{\lambda \in \text{Spec}(T)} m_\lambda (s - \lambda)^{-z}.$$

Suitable conditions for the convergence of these expressions in the case of the local factors are described in [65].

Deninger showed that (4.39) can be written equivalently in the form

$$(4.46) \quad L_\varphi(H^m(X), s)^{-1} = \det_\infty(s - \Theta_q),$$

for an operator with spectrum

$$(4.47) \quad \text{Spec}(s - \Theta_q) = \left\{ \frac{2\pi i}{\log q} \left(\frac{\log q}{2\pi i} (s - \alpha_\lambda) + n \right) : n \in \mathbb{Z}, \lambda \in \text{Spec}(Fr_v^*) \right\},$$

with multiplicities d_λ and with $q^{\alpha_\lambda} = \lambda$.

Moreover, the local factor (4.42) at infinity can be written similarly in the form

$$(4.48) \quad L(H^q(X), s) = \det_\infty\left(\frac{1}{2\pi}(s - \Phi)|_{\mathcal{H}^m}\right)^{-1}$$

where \mathcal{H}^m is an infinite dimensional vector space and Φ is a linear operator with spectrum $\text{Spec}(\Phi) = \mathbb{Z}$ and finite multiplicities. This operator is regarded as a “logarithm of Frobenius” at arithmetic infinity.

Given Deninger’s formulae (4.46) and (4.48), it is natural to ask for a cohomological interpretation of the data

$$(4.49) \quad (\mathcal{H}^m, \Phi)$$

somewhat analogous to (4.40).

7.2. Arithmetic surfaces: L -factor and Dirac operator. Let us now return to the special case of arithmetic surfaces, in the case of genus $g \geq 2$.

At an archimedean prime, we consider the Riemann surface $X_\alpha(\mathbb{C})$ with a Schottky uniformization

$$X(\mathbb{C}) = \Omega_\Gamma/\Gamma.$$

In the case of a real embedding we can assume that the choice of Schottky uniformization is the one that corresponds to the real structure, obtained by cutting $X(\mathbb{C})$ along the real locus $X(\mathbb{R})$.

Consider the spectral triple $(\mathcal{O}_A, \mathcal{H}, \mathcal{D})$ associated to the Schottky group Γ acting on its limit set Λ_Γ . Since the spectral triple is not finitely summable, we do not have zeta functions of the spectral triple in the form $\text{Tr}(a|\mathcal{D}|^z)$. However, we can consider the restriction of \mathcal{D} to a suitable subspace of \mathcal{H} , where it becomes of trace class.

In particular, consider the zeta function

$$(4.50) \quad \zeta_{\pi_{\mathcal{V}}, \mathcal{D}}(s, z) := \sum_{\lambda \in \text{Spec}(\mathcal{D})} \text{Tr}(\pi_{\mathcal{V}} \Pi(\lambda, \mathcal{D})) (s - \lambda)^{-z}$$

where $\pi_{\mathcal{V}}$ is the orthogonal projection of \mathcal{H} onto the subspace \mathcal{V} of $0 \oplus \mathcal{L} \subset \mathcal{H}$ defined by

$$(4.51) \quad \Pi_n \pi_{\mathcal{V}} \Pi_n = \sum_{i=1}^g S_i^n S_i^{*n},$$

on \mathcal{L} , where Π_n are the spectral projections of the Dirac operator, $\Pi_n = \Pi(-n, \mathcal{D})$, for $n \geq 0$.

In the case of an arithmetic surface the interesting local factor is the one for the first cohomology, $L(H^1(X), s)$. This can be computed ([36], [38]) from the zeta function (4.50) of the spectral triple $(\mathcal{O}_A, \mathcal{H}, \mathcal{D})$.

THEOREM 7.1. *The local L -factor (4.42) is given by*

$$(4.52) \quad L(H^1(X), s) = \exp \left(-\frac{d}{dz} \zeta_{\pi_{\mathcal{V}}, \frac{\mathcal{D}}{2\pi}} \left(\frac{s}{2\pi}, z \right) \Big|_{z=0} \right)^{-1}.$$

In case of a real embedding, the same holds, with the projection $\pi_{\mathcal{V}, \bar{F}_\infty = id}$ onto $+1$ eigenspace of the involution \bar{F}_∞ induced by the real structure on \mathcal{V} .

This result shows in particular that, for the special case of arithmetic surfaces with $X(\mathbb{C})$ of genus $g \geq 2$, the pair

$$(4.53) \quad (\mathcal{V} \subset \mathcal{L}, \mathcal{D}|_{\mathcal{V}})$$

is a possible geometric construction of the pair (\mathcal{H}^1, Φ) of (4.49). In particular, the Dirac operator of the spectral triple has an arithmetic meaning, in as it recovers the “logarithm of Frobenius”

$$(4.54) \quad \mathcal{D}|_{\mathcal{V}} = \Phi.$$

If we look more closely at the subspace \mathcal{V} of the Hilbert space \mathcal{H} , we see that it has a simple geometric interpretation in terms of the geodesics in the handlebody \mathfrak{X}_Γ . Remember that the filtered subspace \mathcal{P} of $\mathcal{L} = L^2(\Lambda_\Gamma, d\mu)$ describes 1-cochains on the mapping torus \mathcal{S}_T , with $\mathcal{P}/\delta\mathcal{P} = H^1(\mathcal{S}_T)$.

The mapping torus \mathcal{S}_T is a copy of the tangle of bounded geodesics inside \mathfrak{X}_Γ . Among these geodesics there are g “fundamental” closed geodesics that correspond to the generators of Γ (they correspond to geodesics in \mathbb{H}^3 connecting the fixed points $\{z^\pm(\gamma_i)\}$, for $i = 1, \dots, g$). Topologically, these are the g core handles of the handlebody \mathfrak{X}_Γ and they generate the homology $H_1(\mathfrak{X}_\Gamma)$.

Consider the cohomology $H^1(\mathcal{S}_T)$. Suppose that we wish to find elements of $H^1(\mathcal{S}_T)$ supported on these fundamental closed geodesics. This is impossible, because forms on \mathcal{S}_T are defined by functions in $C(\mathcal{S}, \mathbb{Z})$, that are supported on some clopen set covering the totally disconnected set \mathcal{S} , which contains no isolated points. However, it is possible to choose a sequence of 1-cochains on \mathcal{S}_T whose supports are smaller and smaller clopen sets containing the infinite word in \mathcal{S} corresponding to one of the g fundamental geodesics. The finite dimensional subspace $\mathcal{V}_n = \mathcal{V} \cap \mathcal{P}_n$

$$\mathcal{V}_n \subset \mathcal{P}_n \quad \dim \mathcal{V}_n = 2g$$

gives representatives of exactly such cohomology classes in $H^1(\mathcal{S}_T)$. (We get $2g$ instead of g because we take into account the two possible choices of orientation.)

Thus, this gives us, in the case of arithmetic surfaces, a cohomological interpretation of the space $\mathcal{H}^1 = \mathcal{V}$ in the pair (4.49). Moreover, the Schottky uniformization also provides us with a way of expressing this cohomology $\mathcal{H}^1 = \mathcal{V}$ in terms of the de Rham cohomology $H^1(X(\mathbb{C}))$. In fact, we have already seen in the calculation of the Green function that, under the hypothesis that $\dim_H(\Lambda_\Gamma) < 1$, to each generator γ_i of the Schottky group we can associate a holomorphic differential on the Riemann surface $X(\mathbb{C})$ by (4.24). The map

$$\gamma_i \mapsto \omega_{\gamma_i} = \sum_{h \in C(\gamma_i)} d \log \langle h z^+(\gamma_i), h z^-(\gamma_i), z, z_0 \rangle$$

thus gives an identification

$$(4.55) \quad \mathcal{V} \simeq \bigoplus_{n \in \mathbb{Z}_{\geq 0}} H^1(X(\mathbb{C})).$$

We’ll see in the next section that, in fact, the right hand side of (4.55) is a particular case of a more general construction that works for arithmetic varieties in any dimensions and that gives a cohomological interpretation of (4.49).

FIGURE 15. Vanishing cycles

8. Archimedean cohomology

Consani gave in [35], for general arithmetic varieties (in any dimension), a cohomological interpretation of the pair (\mathcal{H}^m, Φ) in Deninger's calculation of the archimedean L -factors as regularized determinants.

Her construction was motivated by the analogy between geometry at arithmetic infinity and the classical geometry of a degeneration over a disk. She introduced a double complex of differential forms with an endomorphism N representing the “logarithm of the monodromy” around the special fiber at arithmetic infinity, which is modelled on (a resolution of) the complex of *nearby cycles* in the geometric case. The definition of the complex of nearby cycles and of its resolution, on which the following construction is modelled is rather technical. What is easier to visualize geometrically is the related complex of the *vanishing cycles* of a geometric degeneration (Figure 15).

We describe here the construction of [35] using the notation of [40]. We construct the cohomology theory underlying (4.49) in several steps.

In the following we let $X = X(\mathbb{C})$ be a complex compact Kähler manifold.

Step 1: We begin by considering a doubly infinite graded complex

$$(4.56) \quad C = \Omega(X) \otimes \mathbb{C}[U, U^{-1}] \otimes \mathbb{C}[\hbar, \hbar^{-1}],$$

where $\Omega(X)$ is the de Rham complex of differential forms on X , while U and \hbar are formal variables, with U of degree two and \hbar of degree zero.

On this complex we consider differentials

$$(4.57) \quad d'_C := \hbar d, \quad d''_C = \sqrt{-1}(\bar{\partial} - \partial),$$

with total differential $\delta_C = d'_C + d''_C$.

We also have an inner product

$$(4.58) \quad \langle \alpha \otimes U^r \otimes \hbar^k, \eta \otimes U^s \otimes \hbar^t \rangle := \langle \alpha, \eta \rangle \delta_{r,s} \delta_{k,t}$$

where $\langle \alpha, \eta \rangle$ is the usual Hodge inner product of forms,

$$(4.59) \quad \langle \alpha, \eta \rangle = \int_X \alpha \wedge *C(\bar{\eta}),$$

with $C(\eta) = (\sqrt{-1})^{p-q}$, for $\eta \in \Omega^{p,q}(X)$.

Step 2: We use the Hodge filtration

$$(4.60) \quad F^p \Omega^m(X) := \bigoplus_{p'+q=m, p' \geq p} \Omega^{p',q}(X)$$

to define linear subspaces of (4.56) of the form

$$(4.61) \quad \mathfrak{C}^{m,2r} = \bigoplus_{\substack{p+q=m \\ k \geq \max\{0, 2r+m\}}} F^{m+r-k} \Omega^m(X) \otimes U^r \otimes \hbar^k$$

and the \mathbb{Z} -graded vector space

$$(4.62) \quad \mathfrak{C} = \bigoplus_{\cdot = m+2r} \mathfrak{C}^{m,2r}.$$

Step 3: We pass to a real vector space by considering

$$(4.63) \quad \mathcal{T} = (\mathfrak{C})^{c=id},$$

where c denotes complex conjugation.

In terms of the intersection of the Hodge filtrations

$$(4.64) \quad \gamma = F \cap \bar{F}$$

we can write (4.63) as

$$\mathcal{T} = \bigoplus_{\cdot = m+2r} \mathcal{T}^{m,2r}$$

where

$$(4.65) \quad \mathcal{T}^{m,2r} = \bigoplus_{\substack{p+q=m \\ k \geq \max\{0, 2r+m\}}} \gamma^{m+r-k} \Omega^m(X) \otimes U^r \otimes \hbar^k.$$

The \mathbb{Z} -graded complex vector space \mathfrak{C} is a subcomplex of C with respect to the differential d'_C , and for P^\perp the orthogonal projection onto \mathfrak{C} in the inner product (4.58), we obtain a second differential $d'' = P^\perp d''_C$. Similarly, $d' = d'_C$ and $d'' = P^\perp d''_C$ define differentials on

FIGURE 16. Cutoffs defining the complex at arithmetic infinity

the \mathbb{Z} -graded real vector space \mathcal{T}^\cdot , since the inner product (4.58) is real on real forms and induces an inner product on \mathcal{T}^\cdot . We write $\delta = d' + d''$ for the total differential.

We can describe the real vector spaces \mathcal{T}^\cdot in terms of certain cutoffs on the indices of the complex C^\cdot . Namely, for

$$(4.66) \quad \Lambda_{p,q} = \{(r, k) \in \mathbb{Z}^2 : k \geq \kappa(p, q, r)\}$$

with

$$(4.67) \quad \kappa(p, q, r) := \max \left\{ 0, 2r + m, \frac{|p - q| + 2r + m}{2} \right\}$$

(cf. Figure 16), we identify \mathcal{T}^\cdot as a real vector space with the span

$$(4.68) \quad \mathcal{T}^\cdot = \mathbb{R}\langle \alpha \otimes U^r \otimes \hbar^k \rangle,$$

where $(r, k) \in \Lambda_{p,q}$ for $\alpha = \xi + \bar{\xi}$, with $\xi \in \Omega^{p,q}(X)$.

8.1. Operators. The complex $(\mathcal{T}^\cdot, \delta)$ has some interesting structures given by the action of certain linear operators.

We have the operators N and Φ that correspond to the “logarithm of the monodromy” and the “logarithm of Frobenius”. These are of

the form

$$(4.69) \quad N = U\hbar \quad \Phi = -U \frac{\partial}{\partial U}$$

and they satisfy $[N, d'] = [N, d''] = 0$ and $[\Phi, d'] = [\Phi, d''] = 0$, hence they induce operators in cohomology.

Moreover, there is another important operator, which corresponds to the Lefschetz operator on forms,

$$(4.70) \quad \mathbb{L} : \eta \otimes U^r \otimes \hbar^k \mapsto \eta \wedge \omega \otimes U^{r-1} \otimes \hbar^k,$$

where ω is the Kähler form on the manifold X . This satisfies $[\mathbb{L}, d'] = [\mathbb{L}, d''] = 0$, so it also descends on the cohomology.

The pairs of operators N and Φ or \mathbb{L} and Φ satisfy the interesting commutation relations

$$[\Phi, N] = -N, \quad [\Phi, \mathbb{L}] = \mathbb{L}$$

that can be seen as an action of the ring of differential operators

$$\mathbb{C}[P, Q]/(PQ - QP = Q).$$

8.2. $\mathrm{SL}(2, \mathbb{R})$ Representations. Another important piece of the structure of (\mathcal{T}, δ) are two involutions

$$(4.71) \quad S : \alpha \otimes U^r \otimes \hbar^{2r+m+\ell} \mapsto \alpha \otimes U^{-(r+m)} \otimes \hbar^\ell$$

$$(4.72) \quad \tilde{S} : \alpha \otimes U^r \otimes \hbar^k \mapsto C(*\alpha) \otimes U^{r-(n-m)} \otimes \hbar^k.$$

These maps, together with the nilpotent operators N and \mathbb{L} define two representations of $\mathrm{SL}(2, \mathbb{R})$. In terms of

$$(4.73) \quad \begin{aligned} \nu(s) &:= \begin{pmatrix} s & 0 \\ 0 & s^{-1} \end{pmatrix} \quad s \in \mathbb{R}^* \\ u(t) &:= \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix} \quad t \in \mathbb{R} \\ w &:= \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \end{aligned}$$

the representations σ^L and σ^R are given by

$$(4.74) \quad \begin{aligned} \sigma^L(\nu(s)) &= s^{-n+m} & \sigma^R(\nu(s)) &= s^{2r+m} \\ \sigma^L(u(t)) &= \exp(t\mathbb{L}) & \sigma^R(u(t)) &= \exp(tN) \\ \sigma^L(w) &= (\sqrt{-1})^n C \tilde{S} & \sigma^R(w) &= C S. \end{aligned}$$

Of these representations, σ^L extends to an action by bounded operators on the Hilbert completion of \mathcal{T} in the inner product (4.58),

while the action of the subgroup $\nu(s)$, $s \in \mathbb{R}^*$ of $\mathrm{SL}(2, \mathbb{R})$ via the representation σ^R on this Hilbert space is by unbounded densely defined operators.

8.3. Renormalization group and monodromy. This very general structure, which exists for varieties in any dimension, also has interesting connections to noncommutative geometry. For instance, we can see that in fact the map N does play the role of the “logarithm of the monodromy” using an analog in our context of the theory of renormalization à la Connes–Kreimer [28].

In the classical case of a geometric degeneration on a disk, the monodromy around the special fiber is defined as the map

$$(4.75) \quad T = \exp(-2\pi\sqrt{-1} \operatorname{Res}_0(\nabla))$$

where

$$(4.76) \quad N = \operatorname{Res}_0(\nabla)$$

is the residue at zero of the connection, acting as an endomorphism of the cohomology.

In our setting, we consider loops ϕ_μ with values in the group $G = \operatorname{Aut}(\mathcal{T}_{\mathbb{C}}, \delta)$, depending on a “mass parameter” $\mu \in \mathbb{C}^*$. Here $\mathcal{T}_{\mathbb{C}}$ is the complexification of the real vector space \mathcal{T} . The Birkhoff decomposition of a loop ϕ_μ consists in the multiplicative decomposition

$$(4.77) \quad \phi_\mu(z) = \phi_\mu^-(z)^{-1} \phi_\mu^+(z),$$

for $z \in \partial\Delta \subset \mathbb{P}^1(\mathbb{C})$, where Δ is a small disk centered at zero. Of the two terms in the right hand side of (4.77), ϕ_μ^+ extends to a holomorphic function on Δ and ϕ_μ^- to a holomorphic functions on $\mathbb{P}^1(\mathbb{C}) \setminus \Delta$ with values in G . We normalize (4.77) by requiring that $\phi_\mu^-(\infty) = 1$.

By analogy with the Connes–Kreimer theory of renormalization we require the following properties of (4.77):

- The time evolution

$$(4.78) \quad \theta_t : a \mapsto e^{-t\Phi} a e^{t\Phi}$$

acts by scaling

$$(4.79) \quad \phi_{\lambda\mu}(\epsilon) = \theta_{t\epsilon} \phi_\mu(\epsilon),$$

for $\lambda = e^t \in \mathbb{R}_+^*$ and $\epsilon \in \partial\Delta$.

- The term $\phi_\mu^- = \phi^-$ in the Birkhoff decomposition is independent of the energy scale μ .

The residue of a loop ϕ_μ , as in [28], is given by

$$(4.80) \quad \operatorname{Res} \phi = \frac{d}{dz} (\phi^-(1/z)^{-1})|_{z=0}$$

and the beta function of renormalization is

$$(4.81) \quad \beta = \Upsilon \operatorname{Res} \phi, \quad \text{with} \quad \Upsilon = \frac{d}{dt} \theta_t|_{t=0}.$$

In our setting, there is a natural choice of the time evolution, given by the “geodesic flow” associated to the “Dirac operator” Φ , namely

$$(4.82) \quad \theta_t(a) = e^{-t\Phi} a e^{t\Phi}.$$

This gives

$$(4.83) \quad \Upsilon(a) = \frac{d}{dt} \theta_t(a)|_{t=0} = [a, \Phi].$$

There is a *scattering formula* ([28]), by which one can reconstruct ϕ^- from the residue. Namely, we can write

$$\phi^-(z)^{-1} = 1 + \sum_{k \geq 1} d_k z^{-k},$$

with

$$(4.84) \quad d_k = \int_{s_1 \geq \dots \geq s_k \geq 0} \theta_{-s_1}(\beta) \cdots \theta_{-s_k}(\beta) ds_1 \cdots ds_k.$$

The *renormalization group* is given by

$$(4.85) \quad \rho(\lambda) = \lim_{\epsilon \rightarrow 0} \phi^-(\epsilon) \theta_{t\epsilon}(\phi^-(\epsilon)^{-1}),$$

for $\lambda = e^t \in \mathbb{R}_+^*$.

Thus, we only need to specify the residue in order to have the corresponding renormalization theory associated to $(\mathcal{T}_{\mathbb{C}}, \delta)$. By analogy to the case of the geometric degeneration (4.76) it is natural to require that $\operatorname{Res} \phi = N$. We then have ([40]):

PROPOSITION 8.1. *A loop ϕ_μ in $G = \operatorname{Aut}(\mathcal{T}_{\mathbb{C}}, \delta)$ with $\operatorname{Res} \phi_\mu = N$, subject to (4.79) and with ϕ^- independent of μ , satisfies*

$$\phi_\mu(z) = \exp\left(\frac{\mu^z}{z} N\right)$$

with *Birkhoff decomposition*

$$\phi_\mu(z) = \exp(-N/z) \exp\left(\frac{\mu^z - 1}{z} N\right).$$

In fact, by (4.83) and $\operatorname{Res} \phi_\mu = N$ we have $\beta = [N, \Phi] = N$ and $\theta_t(N) = e^t N$, hence the scattering formula (4.84) gives

$$\phi^-(z) = \exp(-N/z)$$

and the scaling property (4.79) determines

$$\phi_\mu(z) = \exp\left(\frac{\mu^z}{z} N\right).$$

The part of the Birkhoff decomposition that is regular at $z = 0$ satisfies $\phi_\mu^+(0) = \mu^N$.

The renormalization group is of the form

$$(4.86) \quad \rho(\lambda) = \lambda^N = \exp(tN),$$

which, through the representation σ^R of $\mathrm{SL}(2, \mathbb{R})$, corresponds to the horocycle flow on $\mathrm{SL}(2, \mathbb{R})$

$$\rho(\lambda) = u(t) = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}.$$

The Birkhoff decomposition (4.77) gives a trivialization of a principal G -bundle over $\mathbb{P}^1(\mathbb{C})$. We can consider the associated vector bundle \mathcal{E}_μ with fiber $\mathcal{T}_{\mathbb{C}}$.

Moreover, we obtain a Fuchsian connection ∇_μ on this bundle,

$$(4.87) \quad \nabla_\mu : \mathcal{E}_\mu \rightarrow \mathcal{E}_\mu \otimes_{\mathcal{O}_\Delta} \Omega_\Delta(\log 0),$$

where the notation $\Omega_\Delta(\log 0)$ denotes forms with logarithmic poles at 0. This has the form

$$\nabla_\mu = N \left(\frac{1}{z} + \frac{d}{dz} \frac{\mu^z - 1}{z} \right) dz,$$

with local gauge potentials

$$-\phi^+(z)^{-1} \frac{\log \pi(\gamma) dz}{z} \phi^+(z) + \phi^+(z)^{-1} d\phi^+(z)$$

with respect to the monodromy representation

$$\pi : \pi_1(\Delta^*) = \mathbb{Z} \rightarrow G$$

given by

$$(4.88) \quad \pi(\gamma) = \exp(-2\pi\sqrt{-1} N)$$

for γ the generator of $\pi_1(\Delta^*)$. This corresponds to (4.75) in the classical geometric case. This Fuchsian connection has residue

$$\mathrm{Res}_{z=0} \nabla_\mu = N$$

as in the geometric case (4.76).

8.4. Local factor and archimedean cohomology. In [35] Con-
sani showed that the data (\mathcal{H}^m, Φ) of (4.49) can be identified with

$$(\mathbb{H}(\mathcal{T}, \delta)^{N=0}, \Phi),$$

where $\mathbb{H}(\mathcal{T}, \delta)$ is the hypercohomology (the cohomology with respect to the total differential δ) of the complex \mathcal{T} and $\mathbb{H}(\mathcal{T}, \delta)^{N=0}$ is the kernel of the map induced by N on cohomology. The operator Φ is the one induced on cohomology by that of (4.69). She called $\mathcal{H}^m \simeq \mathbb{H}(\mathcal{T}, \delta)^{N=0}$ the *archimedean cohomology*.

This can also be viewed (cf. [35]) as a piece of the cohomology of the cone of the monodromy N . This is the complex

$$(4.89) \quad \text{Cone}(N) = \mathcal{T} \oplus \mathcal{T}[+1]$$

with differential

$$D = \begin{pmatrix} \delta & -N \\ 0 & \delta \end{pmatrix}.$$

The complex (4.89) inherits a positive definite inner product from \mathcal{T} , which descends on cohomology. The representation σ^L of $\text{SL}(2, \mathbb{R})$ on \mathcal{T} induces a representation on $\text{Cone}(N)$. The corresponding representation $d\sigma^L : \mathfrak{g} \rightarrow \text{End}(\mathcal{T})$ of the Lie algebra $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{R})$ extends to a representation of the universal enveloping algebra $U(\mathfrak{g})$ on \mathcal{T} and on $\text{Cone}(N)$. This gives a representation in the algebra of bounded operators on the Hilbert completion of $\text{Cone}(N)$ in the inner product.

THEOREM 8.2. *The triple*

$$(\mathcal{A}, \mathcal{H}, \mathcal{D}) = (U(\mathfrak{g}), \mathbb{H}(\text{Cone}(N)), \Phi)$$

has the properties that $\mathcal{D} = \mathcal{D}^$ and that $(1 + \mathcal{D}^2)^{-1/2}$ is a compact operator. The commutators $[\mathcal{D}, a]$ are bounded operators for all $a \in U(\mathfrak{g})$ and the triple is 1^+ -summable.*

Thus, $(\mathcal{A}, \mathcal{H}, \mathcal{D})$ has most of the properties of a spectral triple, confirming the fact that the logarithm of Frobenius Φ should be thought of as a Dirac operator. However, we are not dealing here with an involutive subalgebra of a C^* -algebra.

In any case, the structure is sufficient to consider zeta functions for this “spectral triple”. In particular, we can recover the alternating products of the local L -factors at infinity from a zeta function of the spectral triple.

THEOREM 8.3. *Consider the zeta function*

$$\zeta_{a, \Phi}(z) = \text{Tr}(a|\Phi|^{-z})$$

with $a = \sigma^L(w)$. This gives

$$\det_{\infty, \sigma^L(w), \Phi} (s) = \prod_{m=0}^{2n} L(H^m(X), s)^{(-1)^m}.$$

8.5. Arithmetic surfaces: homology and cohomology. In the particular case of arithmetic surfaces, there is an identification ([35], [36])

$$(4.90) \quad \mathbb{H}(\text{Cone}(N)) \simeq \mathcal{H} \oplus \check{\mathcal{H}},$$

where \mathcal{H} is the archimedean cohomology and $\check{\mathcal{H}}$ is its dual under the involution S of (4.71).

We can then extend the identification

$$U : \mathcal{H}^1 \xrightarrow{\cong} \mathcal{V} \subset \mathcal{L}$$

of (4.55), by considering a subspace \mathcal{W} of the homology $H_1(\mathcal{S}_T)$ with $\mathcal{W} \simeq \check{\mathcal{H}}$. The homology $H_1(\mathcal{S}_T)$ can also be computed as a direct limit

$$H_1(\mathcal{S}_T, \mathbb{Z}) = \varinjlim_N \mathcal{K}_N,$$

where the \mathcal{K}_N are free abelian of rank $(2g-1)^N + 1$ for N even and $(2g-1)^N + (2g-1)$ for N odd. The \mathbb{Z} -module \mathcal{K}_N is generated by the closed geodesics represented by periodic sequences in \mathcal{S} of period $N+1$. These need not be primitive closed geodesics. In terms of primitive closed geodesics we can write equivalently

$$H_1(\mathcal{S}_T, \mathbb{Z}) = \bigoplus_{N=0}^{\infty} \mathcal{R}_N$$

where the \mathcal{R}_N are free abelian groups with

$$\text{rk } \mathcal{R}_N = \frac{1}{N} \sum_{d|N} \mu(d) \text{rk } \mathcal{K}_{N/d},$$

with $\mu(d)$ the Möbius function satisfying $\sum_{d|N} \mu(d) = \delta_{N,1}$.

The pairing of homology and cohomology is given by

$$\langle \cdot, \cdot \rangle : F_n \times \mathcal{K}_N \rightarrow \mathbb{Z} \quad \langle [f], x \rangle = N \cdot f(\bar{x}).$$

This determines a graded subspace $\mathcal{W} \subset H_1(\mathcal{S}_T, \mathbb{Z})$ dual to $\mathcal{V} \subset H^1(\mathcal{S}_T)$. With the identification

$$\begin{array}{ccc} \mathcal{H}^1 & \xrightarrow{U} & \mathcal{V} \subset H^1(\mathcal{S}_T) \\ \downarrow S & & \downarrow \langle \cdot, \cdot \rangle \\ \check{\mathcal{H}}^1 & \xrightarrow{U} & \mathcal{W} \subset H_1(\mathcal{S}_T), \end{array}$$

we can identify the Dirac operator of (4.16) with the logarithm of Frobenius

$$(4.91) \quad \mathcal{D}|_{\mathcal{V} \oplus \mathcal{V}} = \Phi_{\mathcal{H}^1 \oplus \check{\mathcal{H}}^1}.$$
