# 4.5. Absolute Maxima and Minima DEFINITIONS

y = f(x) is a function with domain $D$ .	
(1) $f$ has an	OT
$at x = c  ext{ if } f(c) \ge f(x)  ext{ for all } x  ext{ in } D. f(c)  ext{ is the } \$	
(2) <i>f</i> has an	OT
$at x = c  ext{ if } f(c) \le f(x)  ext{ for all } x  ext{ in } D. f(c)  ext{ is the } \$	
(3) The minimum and maximum values are called of $f$ .	the
(4) <i>f</i> has an	OT
$at x = c \text{ if } f(c) \ge f(x) \text{ for } x$ "close enough" to $c. f(c) \text{ is the } \_$	
(5) $f$ has an	OT
$at x = c \text{ if } f(c) \le f(x) \text{ for } x$ "close enough" to $c. f(c) \text{ is the } \$	
(6) "close enough" to $c$ means there is an open interval around $c$ where the statement is true. This open interval can be very small.	

(7) The local minimum and local maximum values are called the \_\_\_\_\_\_ of f.

#### Section 4.5

### 4.5. Examples

**Example 4.5.2.** Select ALL the correct choices  $f(x) = 2 - 4x - \frac{4}{x}$  over the interval  $(-\infty,0)$ 

- (1) f(x) has no maximum (2) f(x) has no minimum
- (3) f(x) has an absolute maximum at x = -1
- (4) f(x) has an absolute minimum at x = -1
- (5) f(x) has an absolute maximum of 2
- (6) f(x) has an absolute minimum of 2

#### Section 4.5

## Useful Theorems

**Theorem 4.5.1** (Second Derivative Test). Suppose y = f(x) is such that f'(c) = 0 (and f is twice differentiable around c).

(1) If f''(c) > 0 then \_\_\_\_\_\_

(2) If f''(c) < 0 then \_\_\_\_\_

(3) If f''(c) = 0 or f''(x) does not exist, then \_\_\_\_\_

**Theorem 4.5.2.** If f(x) has only one critical number in some interval I, then statements (1) and (2) in Theorem 4.5.1 are <u>absolute</u> extrema.

**Example 4.5.3.** Find the local extrema of the function of  $f(x) = x^3 - 4x^2 - 3x - 10$  using the second derivative test.

**Example 4.5.4.** If f(x) is continuous on  $(-\infty, \infty)$  such that f'(7) = 0 and f''(7) = -2, then

- a) f(x) has a local maximum at x = 7
- b) f(x) has a local minimum at x = 7
- c) f(x) has no local extrema at x = 7
- d) we are unable to determine if there is a local extrema at x = 7

**Example 4.5.5.** If f(x) is continuous on  $(-\infty, \infty)$  such that f'(7) = 1 and f''(7) < 0, then

- a) f(x) has a local maximum at x = 7
- b) f(x) has a local minimum at x = 7
- c) f(x) has no local extrema at x = 7
- d) we are unable to determine if there is a local extrema at x = 7

**Example 4.5.6.** Find the absolute extrema of  $f(x) = 5 \ln x - x$  over  $(0, \infty)$ 

**Example 4.5.7.** Find the the absolute extrema of  $f(x) = 4x^4 - 5$ .

**Theorem 4.5.3** (The Extreme Value Theorem). If f is continuous on the closed interval [a, b], then f will attain a minimum and a maximum in the interval.

In other words, if you consider the interval [a, b] as the domain of f, there will be at least one number c in [a, b] where f(c) is the maximum, and at least one number d in [a, b] where f(d) is the minimum.

## Closed Interval Method

To find the *absolute* minimum and maximum values of a *continuous* function f on a *closed interval* [a, b]:

- Step 1. Find the critical numbers of f in (a, b).
- Step 2. Find the function value at all critical value(s) found in step 1.

Step 3. Find f(a) and f(b).

Step 4. The largest value from steps 2 and 3 is the maximum value and the smallest value from steps 2 and 3 is the minimum value.

## Examples

**Example 4.5.8.** Find all critical values and absolute extrema on the given interval.

 $f(x) = 6x - x^2, [-1, 4]$ 

- (1) min value is -7, max value is 9
- (2) min value is -7, max value is 40
- (3) min value is -5, max value is 8
- (4) min value is -5, max value is 40

Example 4.5.9. Find all critical values and absolute extrema on the given interval.

$$f(x) = \frac{x^2 - 4}{x^2 + 4}, \ [-4, 4]$$

**Example 4.5.10.** Find all the absolute extrema of  $f(x) = \ln x$  over the interval [1, 2].
